**Abstract.** We describe a cryptanalysis of a public-key encryption scheme based on the polynomial reconstruction problem, published at Eurocrypt 2003 by Augot and Finiasz. Given the public-key and a ciphertext, we recover the corresponding plaintext in polynomial time. Our technique is a variant of the Berlekamp-Welsh algorithm. We also describe a cryptanalysis of the reparation published by the authors on the IACR eprint archive, using a variant of the previous attack. Both attacks are practical as given the public-key and a ciphertext, one recovers the plaintext in a few minutes on a single PC.

**Key-Words:** Cryptanalysis, Augot and Finiasz cryptosystem, Polynomial Reconstruction Problem, Reed-Solomon codes.

## 1 Introduction

We describe a cryptanalysis of a public-key encryption scheme recently proposed by Augot and Finiasz [1]. The scheme is based on the polynomial reconstruction (PR) problem [10], which is the following:

*Problem 1 (Polynomial Reconstruction).* Given  $n, k, \omega$  and  $(x_i, y_i)_{i=1\dots n}$ , output any polynomial  $p$  such that  $\deg p < k$  and  $p(x_i) = y_i$  for at least  $n - \omega$  values of  $i$ .

This problem has an equivalent formulation in terms of the decoding of Reed-Solomon error-correcting codes [11]. The problem can be solved in polynomial time when the number of errors  $\omega$  is such that  $\omega \leq (n - k)/2$ , using the Berlekamp-Welsh algorithm [3]. This has been improved to  $\omega \leq n - \sqrt{kn}$  by Guruswami and Sudan [7].

When the number of errors is larger, no polynomial time algorithm is known for the PR problem. Therefore, some cryptosystem have been constructed based

on the hardness of the PR problem; for example, an oblivious polynomial evaluation scheme [10], and a semantically secure symmetric cipher [8].

At Eurocrypt 2003, Augot and Finiasz proposed a new public-key encryption scheme based on the polynomial reconstruction problem [1]. A security level exponential in terms of the parameters was conjectured. However, we provide a complete cryptanalysis of the cryptosystem: given the public key  $pk$  and a ciphertext  $c$ , we recover the corresponding plaintext  $m$  in polynomial time. Therefore, the scheme is not one-way and cannot be used in any application. Our technique is a variant of the Berlekamp-Welsh algorithm [3] for solving the PR problem.

After the publication of our attack in the IACR eprint archive [5], a reparation of the cryptosystem was published by Augot, Finiasz and Loidreau in [2]. The reparation is based on the trace operator, and is resistant against the previous attack. However, we describe a new cryptanalysis of the repaired scheme. Given the public-key and a ciphertext, we can still recover the corresponding plaintext in polynomial time. Our technique is again a variant of the Berlekamp-Welsh algorithm. Both attacks work very well in practice, as for the proposed parameters, one recovers the plaintext in a few minutes on a single PC.

## 2 Augot and Finiasz' Cryptosystem

In this section, we recall the original cryptosystem proposed by Augot and Finiasz at Eurocrypt 2003. As in [1], we first recall some basic definitions of Reed-Solomon codes.

### 2.1 Reed-Solomon Codes

Let  $F_q$  be the finite field with  $q$  elements and let  $x_1, \dots, x_n$  be  $n$  distinct elements of  $F_q$ . We denote by  $ev$  the following map:

$$ev : \begin{cases} F_q[X] & \rightarrow F_q^n \\ p(X) & \rightarrow (p(x_1), \dots, p(x_n)) \end{cases}$$

**Definition 1.** *The Reed-Solomon code of dimension  $k$  and length  $n$  over  $F_q$  is the following set of  $n$ -tuples (codewords):*

$$RS_k = \{ev(f); f \in F_q[X], \deg f < k\}$$

where  $F_q[X]$  is the set of univariate polynomials with coefficients in  $F_q$ .

The *weight* of a word  $c \in F_q^n$  is the number of non-zero coordinates in  $c$ . The *Hamming distance* between two words  $x$  and  $y$  is the weight of  $x - y$ . Formally, the problem of decoding Reed-Solomon code is the following:

*Problem 2 (Reed-Solomon decoding).* Given a Reed-Solomon code  $RS_k$  of length  $n$ ,  $\omega$  an integer and a word  $y \in F_q^n$ , find any codeword in  $RS_k$  at distance less than  $\omega$  of  $y$ .

The smallest weight of non-zero codewords in  $RS_k$  is  $n - k + 1$ . Therefore, when  $\omega \leq (n - k)/2$ , the solution to Reed-Solomon decoding is guaranteed to be unique. It is easy to see that the Polynomial Reconstruction problem and the Reed-Solomon decoding problem are equivalent. Both problems can be solved in polynomial time when  $w \leq (n - k)/2$ , using the Berlekamp-Welsh algorithm [3].

## 2.2 Augot and Finiasz' Cryptosystem

In the following, we briefly review Augot and Finiasz public-key cryptosystem [1].

**Parameters:**  $q$  is the size of  $F_q$ ,  $n$  is the length of the Reed-Solomon code,  $k$  its dimension,  $W$  is the weight of a large error, so that the PR problem for  $n, k, W$  is believed to be hard, i.e. we must have:

$$W > \frac{n - k}{2}$$

$\omega$  is the weight of a small error, for which the PR problem with  $n - W$  coordinates is easy:

$$\omega \leq \frac{n - W - k}{2} \quad (1)$$

It is recommended in [1] to take  $n = 1024$ ,  $k = 900$ ,  $\omega = 25$ ,  $W = 74$  and  $q = 2^{80}$ .

**Key generation:** Generate a unitary polynomial  $p$  of degree  $k - 1$ , and a random  $n$ -dimensional vector  $E$  of weight  $W$ . Compute the codeword  $c = ev(p)$  of  $RS_k$ . The public key is  $z = c + E$ , while the private key is  $(p, E)$ .

**Encryption:** Let  $m$  a message of length  $k - 1$  over the alphabet  $F_q$ . The message  $m$  is seen as a polynomial  $m(X) = m_0 + m_1X + \dots + m_{k-1}X^{k-2}$  of degree at most  $k - 2$ . Generate a random  $\alpha \in F_q$  and a random error  $e$  of weight  $\omega$ . The ciphertext  $y$  is then:

$$y = ev(m) + \alpha \times (c + E) + e$$

**Decryption:** One considers only the positions where  $E_i = 0$  and define the shortened code of length  $n - W$ , which is also a Reed-Solomon code of dimension  $k$ , which we denote  $\overline{RS}_k$ . Let  $\overline{y}, \overline{ev}(m), \overline{c}, \overline{e}$  be the shortened  $y, ev(m), c, e$ . One must solve the equation:

$$\overline{y} = \overline{ev}(m) + \alpha \times \overline{c} + \overline{e}$$

We have  $\overline{ev}(m) + \alpha \times \overline{c} \in \overline{RS}_k$ , and from (1), the weight of the small error  $\overline{e}$  is less than the error correction capacity of  $\overline{RS}_k$ ; therefore, using the Berlekamp-Welsh algorithm, one can recover the unique polynomial  $r$  of degree  $k - 1$  such that:

$$ev(r) = \overline{ev}(m) + \alpha \times \overline{c}$$

which gives

$$r = m + \alpha \cdot p$$

Since  $\deg(m) \leq k - 2$  and  $p$  is a unitary polynomial of degree  $k - 1$ , the field element  $\alpha$  is the leading coefficient of  $r$ . Therefore one can recover  $m$  as:

$$m = r - \alpha \cdot p$$

### 3 Our Attack

The attack is a variant of the Berlekamp-Welsh algorithm for solving the PR problem (see [6]).

Let  $n, k, W, \omega$  and  $q$  be the parameters of the system. Let  $(p, E)$  be the private key and  $z = ev(p) + E$  be the public-key. Let  $m$  be the plaintext encoded as a polynomial of degree less than  $k - 2$ . Let  $e$  be an error vector of weight  $\omega$ , and  $\alpha$  be a field element. Let

$$y = ev(m) + \alpha \times z + e \quad (2)$$

be the corresponding ciphertext.

**Theorem 1.** *Given the public-key  $z$  and the ciphertext  $y$ , one can recover the corresponding plaintext  $m$  in polynomial time.*

*Proof.* Let  $y_i, z_i$  and  $e_i$  be the components of the words  $y, z$  and  $e$ . Given  $y$  and  $z$ , one must solve the following set of equations:

$$\exists e, m, \alpha, y_i = m(x_i) + \alpha \cdot z_i + e_i \text{ for all } 1 \leq i \leq n \quad (3)$$

where the weight of  $e$  is less than  $\omega$ . Note that from the definition of the cryptosystem, there is a unique solution.

Consider the following set of equations:

$$\exists V, m, \alpha, \begin{cases} \deg(V) \leq \omega, V \neq 0, \deg(m) \leq k - 2 \\ \forall i, V(x_i) \cdot (y_i - \alpha \cdot z_i) = V(x_i) \cdot m(x_i) \end{cases} \quad (4)$$

Any solution  $V, m, \alpha$  of (4) gives a solution to (3). Namely, the fact that  $V \neq 0$  and  $\deg V \leq \omega$  implies that  $V$  can be equal to zero at most  $\omega$  times. Therefore, letting  $e_i = y_i - m(x_i) - \alpha \cdot z_i$ , the weight of  $e$  is less than  $\omega$ .

Conversely, any solution to (3) gives a solution to (4). Namely, one can take  $V(X) = \prod_{i \in B} (X - x_i)$  with  $B = \{i | e_i \neq 0\}$ . The problem of solving (3) can thus be reduced to finding  $V, m, \alpha$  satisfying (4). Consider now the following set of equations:

$$\exists V, N, \lambda, \begin{cases} \deg(V) \leq \omega, V \neq 0, \deg(N) \leq k + \omega - 1 \\ \forall i, V(x_i) \cdot (y_i - \lambda \cdot z_i) = N(x_i) \end{cases} \quad (5)$$

The system (5) is a linearized version of (4), in which one has replaced the product  $V(x_i) \cdot m(x_i)$  by  $N(x_i)$ . It is easy to see that any solution of (4) gives a solution to (5), as one can take  $\lambda = \alpha$  and  $N = m \cdot V$ . However, the converse is not necessarily true.

For a given  $\lambda$ , the system (5) gives a linear system of  $n$  equations in the  $k + 2 \cdot \omega + 1$  unknown, which are the coefficients of the polynomials  $V$  and  $N$ . More precisely, denoting:

$$V(X) = \sum_{i=0}^{\omega} v_i \cdot X^i, \quad N(X) = \sum_{i=0}^{k+\omega-1} n_i \cdot X^i$$

and  $Y$  the vector of coordinates:

$$Y = (v_0, \dots, v_{\omega}, n_0, \dots, n_{k+\omega-1})$$

one let  $M(\lambda)$  be the matrix of the system:

$$M(\lambda)_{i,j} = \begin{cases} (y_i - \lambda \cdot z_i) \cdot (x_i)^j & \text{if } 0 \leq j \leq \omega \\ -(x_i)^{j-\omega-1} & \text{if } \omega < j < k + 2\omega + 1 \end{cases}$$

The matrix  $M(\lambda)$  is a rectangular matrix with  $n$  lines and  $k + 2\omega + 1$  columns; from (1) we have that  $n > k + 2\omega + 1$ . The coefficients of  $M(\lambda)$  are a function of the public-key and the ciphertext only. The system (5) is then equivalent to:

$$\exists Y, \lambda, \quad M(\lambda) \cdot Y = 0, \quad Y \neq 0 \tag{6}$$

We consider the matrix  $M(\lambda)$  with  $\lambda = 0$ . Using Gaussian elimination, we compute the rank of the matrix  $M(0)$ . We distinguish two cases:  $\text{rank } M(0) = k + 2\omega + 1$ , and  $\text{rank } M(0) < k + 2\omega + 1$ .

If  $\text{rank } M(0) = k + 2\omega + 1$ , then there exists a square sub-matrix of  $M(0)$  of dimension  $k + 2\omega + 1$  which is invertible. Without loss of generality, one can assume that the matrix obtained by taking the first  $k + 2\omega + 1$  lines of  $M(0)$  is invertible. Let  $M'(\lambda)$  be the square matrix obtained by taking the first  $k + 2\omega + 1$  lines of  $M(\lambda)$ . Any solution  $Y, \lambda$  of (6) satisfies:

$$M'(\lambda) \cdot Y = 0, \quad Y \neq 0$$

which implies that the matrix  $M'(\lambda)$  is non-invertible, i.e.  $\det(M(\lambda)) = 0$ . Then, the solution  $\alpha$  in system (4) must be a root of the function:

$$f(\lambda) = \text{Det}(M'(\lambda))$$

which is a polynomial of degree at most  $\omega + 1$ . The polynomial  $f$  is not identically zero, because  $M'(0)$  is invertible, which implies  $f(0) \neq 0$ . The polynomial  $f$  can easily be obtained from the public-key  $z$  and the ciphertext  $y$  by computing  $f(\lambda) = \text{Det}(M'(\lambda))$  for  $\omega + 2$  distinct values of  $\lambda$  and then using Lagrange interpolation.

The factorization of a polynomial over a finite-field can be done in polynomial time (see for example [13]). Therefore, one obtains a list of at most  $\omega + 1$  candidates, one of which being the solution  $\alpha$  of (4), and equivalently, of (3). For the right candidate  $\alpha$ , the vector  $y - \alpha \times z$  is equal to  $ev(m) + e$ , where the weight of  $e$  is less than the error correcting capacity of the Reed-Solomon code. Therefore, using Berlekamp-Welsh algorithm, one recovers the plaintext  $m$  from  $y - \alpha \times z$  in polynomial time.

More precisely, let  $\alpha, m, e$  be the solution of (3). Given a solution  $V, N, \lambda$  of (5) with  $\lambda = \alpha$ , we have for all  $1 \leq i \leq k + 2 \cdot \omega + 1$  :

$$V(x_i) \cdot (m(x_i) + e_i) = N(x_i)$$

Since the error vector  $e$  has a weight at most  $\omega$ , we have for at least  $\omega + k + 1$  values of  $i$ :

$$V(x_i) \cdot m(x_i) = N(x_i)$$

$N$  and  $V \cdot m$  are therefore two polynomials of degree less than  $\omega + k - 1$  which take the same value on at least  $\omega + k + 1$  distinct points; consequently, the two polynomials must be equal. This means that one can recover  $m$  by performing a polynomial division:

$$m = \frac{N}{V}$$

Therefore, one can recover the plaintext in polynomial time.

Let us now consider the second case, *i.e.*  $rank M(0) < k + 2\omega + 1$ . Then there exists  $Y \neq 0$  such that  $M(0) \cdot Y = 0$ . The vector  $Y$  gives the coefficients of two polynomials  $V$  and  $N$  such that for all  $1 \leq i \leq n$ :

$$V(x_i) \cdot y_i = N(x_i)$$

From (2) we have  $y_i = m(x_i) + \alpha \cdot (p(x_i) + E_i) + e_i$ , which gives for all  $i$ :

$$V(x_i) \cdot ((m + \alpha \cdot p)(x_i) + \alpha \cdot E_i + e_i) = N(x_i)$$

The weight of  $E$  is at most  $W$  and the weight of  $e$  is at most  $\omega$ . Moreover, from (1) we have  $n \geq k + 2\omega + W$ . Therefore, for at least  $\omega + k$  values of  $i$ , we have:

$$V(x_i) \cdot (m + \alpha \cdot p)(x_i) = N(x_i)$$

As previously,  $V \cdot (m + \alpha \cdot p)$  and  $N$  are two polynomials of degree less than  $k + \omega - 1$  which take the same value on at least  $\omega + k$  distinct points; consequently, they must be equal, which gives:

$$m + \alpha \cdot p = \frac{N}{V}$$

Since the polynomial  $p$  is unitary and  $\deg p = k - 1$  and  $\deg m \leq k - 2$ , this enables to recover  $\alpha$ . Then, as previously, given  $\alpha$ , we recover  $m$  in polynomial time<sup>1</sup>.  $\square$

<sup>1</sup> In this second case, we can also recover the private key  $(p, E)$ . It has been shown in [9] that this second case happens with negligible probability.

## 4 The Repaired Cryptosystem

In this section, we describe the repaired cryptosystem published in [2]. The new cryptosystem is resistant against the previous attack. The reparation is based on working in the subfield of a given field, and using the trace operator. Following [2], we recall these notions in the next section.

### 4.1 Subfields and Trace Operator

We consider the finite field  $\text{GF}(q^u)$ , where  $q$  is the power of a prime integer. The finite field  $\text{GF}(q)$  is a subfield of  $\text{GF}(q^u)$ . The finite field  $\text{GF}(q^u)$  can be viewed as a  $u$ -dimensional vector space over  $\text{GF}(q)$ . Let  $\gamma_1, \dots, \gamma_u$  be a basis of  $\text{GF}(q^u)$  over  $\text{GF}(q)$ , then every element  $\alpha \in \text{GF}(q^u)$  can be uniquely written  $\alpha = \sum_{i=1}^u \alpha_i \gamma_i$ , where  $\alpha_i \in \text{GF}(q)$ .

**Definition 2.** *The trace operator of  $\text{GF}(q^u)$  into  $\text{GF}(q)$  is defined by:*

$$\forall x \in \text{GF}(q^u), \text{Tr}(x) = x + x^q + \dots + x^{q^{u-1}}$$

The trace operator is a  $\text{GF}(q)$ -linear mapping (and not  $\text{GF}(q^u)$ -linear) of  $\text{GF}(q^u)$  into  $\text{GF}(q)$ . For any basis  $\gamma_1, \dots, \gamma_u$  of  $\text{GF}(q^u)$ , there exists a unique dual basis  $\gamma_1^*, \dots, \gamma_u^*$  with respect to the Trace operator. The dual basis is such that:

$$\text{Tr}(\gamma_i \gamma_j^*) = 1 \text{ if } i = j, \text{ and } 0 \text{ otherwise}$$

The dual basis can be efficiently computed.

We extend the trace operator to vectors:

$$\text{Tr}(c_1, \dots, c_n) = (\text{Tr}(c_1), \dots, \text{Tr}(c_n))$$

and to polynomials: for any polynomial  $p \in \text{GF}(q^u)[X]$ ,  $p(x) = \sum_{i=0}^k p_i x^i$ , we define the polynomial  $\text{Tr}(p) \in \text{GF}(q)[X]$  as:

$$\text{Tr}(p)(x) = \sum_{i=0}^k \text{Tr}(p_i) x^i$$

Let  $x_1, \dots, x_n$  be  $n$  distinct elements of  $\text{GF}(q) \in \text{GF}(q^u)$ . As in section 2.1 we denote by  $ev$  the following map:

$$ev : \begin{cases} \text{GF}(q^u)[X] & \rightarrow \text{GF}(q^u)^n \\ p(X) & \rightarrow (p(x_1), \dots, p(x_n)) \end{cases}$$

**Proposition 1.** *For all  $p \in \text{GF}(q^u)[X]$ , we have  $\text{Tr}(ev(p)) = ev(\text{Tr}(p))$*

*Proof.* The  $j$ -th component of  $\text{Tr}(ev(p))$  is

$$\text{Tr}(p(x_j)) = \text{Tr}\left(\sum_{i=0}^k p_i \cdot (x_j)^i\right)$$

From the  $\text{GF}(q)$ -linearity of the Trace operator and the fact that  $x_j \in \text{GF}(q)$ , we obtain:

$$\text{Tr}(p(x_j)) = \sum_{i=0}^k \text{Tr}(p_i)(x_j)^i$$

which is the  $j$ -th component of  $ev(\text{Tr}(p))$ . □

As in section 2.1, we define the Reed-Solomon code of dimension  $k$  and length  $n$  over  $\text{GF}(q^u)$  as the following set of  $n$ -tuples (codewords):

$$RS_k = \{ev(f); f \in \text{GF}(q^u)[X], \deg f < k\}$$

## 4.2 The Repaired Cryptosystem

In this section, we recall the repaired cryptosystem [2].

**Parameters:** A finite field  $\text{GF}(q^u)$ , an integer  $n$  as the length of the Reed-Solomon code,  $k$  its dimension,  $W$  is the weight of a large error,  $\omega$  is the weight of a small error, for which the PR problem with  $n - W$  coordinates is easy:

$$\omega \leq \frac{n - W - k}{2} \tag{7}$$

The authors of the repaired cryptosystem recommend in [2] to take  $q = 2^{20}$ ,  $u = 4$ ,  $n = 2048$ ,  $k = 1400$ ,  $W = 546$  and  $\omega = 49$ .<sup>2</sup>

**Key generation:** Generate a random polynomial  $p$  of degree  $k-1$  over  $\text{GF}(q^u)$ , such that the  $u$  coefficients  $p_{k-1}, \dots, p_{k-u}$  form a basis of  $\text{GF}(q^u)$  over  $\text{GF}(q)$ . Compute  $c = ev(p) \in RS_k$ . Generate a random  $n$ -dimensional vector  $E$  of weight  $W$  with coefficients in  $\text{GF}(q^u)$ . The public-key is the vector  $K = c + E$  over  $\text{GF}(q^u)$ . The private key is  $(p, E)$ .

**Encryption:** Let  $m$  a message of length  $k - u$  over the alphabet  $\text{GF}(q)$ . The message  $m$  is seen as a polynomial  $m(X) = m_0 + m_1X + \dots + m_{k-u-1}X^{k-u-1}$  in  $\text{GF}(q)[X]$ . Generate a random  $\alpha \in \text{GF}(q^u)$  and a random vector  $e$  of weight  $\omega$  over  $\text{GF}(q)$ . The ciphertext  $y$  is then:

$$y = ev(m) + \text{Tr}(\alpha \cdot K) + e$$

---

<sup>2</sup> Actually, the authors of [2] forgot to clearly specify  $k$ , but they state that with these parameters, “a plaintext consists of  $k - u$  elements in  $\text{GF}(2^{20})$ , that is 27920 bits”, from which we infer that  $k = 27920/20 + 4 = 1400$

**Decryption:** One considers only the positions where  $E_i = 0$  and define the shortened code of length  $n - W$ , which is also a Reed-Solomon code of dimension  $k$ , which we denote  $\overline{RS}_k$ . Let  $\overline{y}, \overline{c}, \overline{e}$  be the shortened  $y, c, e$  and let  $\overline{ev}$  be the shortened map  $ev$ . One must solve the equation:

$$\overline{y} = \overline{ev}(m) + \text{Tr}(\alpha \cdot \overline{c}) + \overline{e}$$

Using proposition 1, we have:

$$\text{Tr}(\alpha \cdot \overline{c}) = \text{Tr}(\alpha \cdot \overline{ev}(p)) = \text{Tr}(\overline{ev}(\alpha p)) = \overline{ev}(\text{Tr}(\alpha p))$$

Thus  $\overline{ev}(m) + \text{Tr}(\alpha \cdot \overline{c}) = \overline{ev}(m + \text{Tr}(\alpha p)) \in \overline{RS}_k$ , and from (7), the weight of the small error  $\overline{e}$  is less than the error correction capacity of  $\overline{RS}_k$ ; therefore, using the Berlekamp-Welsh algorithm, one can recover the polynomial  $q = m + \text{Tr}(\alpha p)$ .

Letting  $q = \sum_{i=0}^{k-1} q_i x^i$ , since  $\deg(m) \leq k - u - 1$ , we have  $q_i = \text{Tr}(\alpha p_i)$  for  $i = k - u, \dots, k - 1$ . This gives the  $u$  coordinates of  $\alpha$  in the dual basis of  $p_{k-u}, \dots, p_{k-1}$ , from which we derive  $\alpha$ . From  $\alpha$  one recovers  $m$  as  $m = q - \text{Tr}(\alpha p)$ .

## 5 The Attack against the Repaired Cryptosystem

In this section, we describe an attack that breaks the repaired cryptosystem. Given the public key and a ciphertext, we recover the plaintext in polynomial time. As the attack of section 3, it is a variant of the Berlekamp-Welsh algorithm, but as opposed to the previous attack, it is only a heuristic (but it works very well in practice).

Let  $\text{GF}(q^u)$ ,  $n, k, W, \omega$  be the parameters of the system. Let  $(p, E)$  be the private key and  $K = ev(p) + E$  be the public-key. Let  $m$  be the plaintext encoded as a polynomial of degree less than  $k - u - 1$ . Let  $e$  be an error vector of weight  $\omega$ , and  $\alpha \in \text{GF}(q^u)$ . Let

$$y = ev(m) + \text{Tr}(\alpha \cdot K) + e$$

be the corresponding ciphertext.

Let  $\gamma_1, \dots, \gamma_u$  be a basis of  $\text{GF}(q^u)$  over  $\text{GF}(q)$ . We write  $\alpha = \sum_{t=1}^u \alpha_t \cdot \gamma_t$  where  $\alpha_t \in \text{GF}(q)$ . We have

$$\text{Tr}(\alpha \cdot K) = \sum_{t=1}^u \alpha_t \text{Tr}(\gamma_t \cdot K)$$

For  $t = 1, \dots, u$ , we define:

$$K_t = \text{Tr}(\gamma_t \cdot K)$$

Note that the  $u$  vectors  $K_t$  are vectors over  $\text{GF}(q)$  which can be computed from the public-key  $K$ . Finally the ciphertext can be written as:

$$y = ev(m) + \sum_{t=1}^u \alpha_t \cdot K_t + e \tag{8}$$

Note that in equation (8), all computation is done in the subfield  $\text{GF}(q)$ . Let  $y_i, K_{t,i}$  and  $e_i$  be the components of the vectors  $y, K_t$  and  $e$ . Given  $y$  and  $K_t$ , one must solve the following set of equations:

$$\exists e, m, \alpha_1, \dots, \alpha_u, y_i = m(x_i) + \sum_{t=1}^u \alpha_t \cdot K_{t,i} + e_i \text{ for all } 1 \leq i \leq n \quad (9)$$

where the weight of  $e$  is  $\omega$ . Note that from the definition of the cryptosystem, there is a unique solution.

Let  $V, R_1, \dots, R_u$  be polynomials of degree at most  $\omega$ , with  $V \neq 0$ . Let  $N$  be a polynomial of degree at most  $\omega + k - u - 1$ . Consider the following set of equations, where the unknown are the polynomials  $V, R_1, \dots, R_u$  and  $N$ :

$$\forall i \in [1, n], V(x_i) \cdot y_i = N(x_i) + \sum_{t=1}^u K_{t,i} \cdot R_t(x_i) \quad (10)$$

It is clear that given a solution to system (9), one can obtain a solution to system (10) with  $V \neq 0$ . Namely, one can take  $V(X) = \prod_{i \in B} (X - x_i)$  with  $B = \{i | e_i \neq 0\}$ , and  $R_t = \alpha_t \cdot V$  for  $t = 1, \dots, u$ , and  $N = m \cdot V$ . This shows that the system (10) has at least a non-zero solution.

The system (10) gives a homogeneous linear system of  $n$  equations in the  $k + (u + 2) \cdot \omega + 1$  unknowns, which are the coefficients of the polynomials  $V, R_1, \dots, R_u$  and  $N$ . Let  $M$  be the matrix of the corresponding system. The matrix has  $k + (u + 2) \cdot \omega + 1$  columns and  $n$  rows and can be computed from the ciphertext and the public-key. In the following, we assume that:

$$n \geq k + (u + 2) \cdot \omega \quad (11)$$

This inequality is valid for the proposed parameters. Since the system (10) has at least a non-zero solution, the matrix cannot be of maximum rank, therefore  $\text{rank } M \leq k + (u + 2) \cdot \omega$ .

In the following, we assume that  $\text{rank } M = k + (u + 2) \cdot \omega$ . This is the only assumption that we make for our cryptanalysis. It seems that in practice, this assumption is always satisfied. In this case, the kernel of  $M$  is a linear space of dimension 1. We have already seen that  $V(X) = \prod_{i \in B} (X - x_i)$  with  $B = \{i | e_i \neq 0\}$ , and  $R_t = \alpha_t \cdot V$  for  $t = 1, \dots, u$  and  $N = m \cdot V$  is a solution to the system (10), and so  $(V, R_1, \dots, R_u, N)$  generates the kernel of  $M$ .

Therefore, if we compute by Gaussian elimination an element  $(V', R'_1, \dots, R'_u, N')$  in  $\ker M$ , we must have that  $V' = \lambda \cdot V$ ,  $R'_t = \lambda R_t$  for  $t = 1, \dots, u$  and  $N' = \lambda \cdot N$  for some  $\lambda \in \text{GF}(q)$  with  $\lambda \neq 0$ . Therefore, we have  $N' = \lambda \cdot N = \lambda \cdot m \cdot V = m \cdot V'$  and we can recover  $m$  by doing a polynomial division:

$$m = \frac{N'}{V'}$$

To summarize, assuming that  $\text{rank } M = k + (u + 2) \cdot \omega$ , we recover the plaintext from the public-key and the ciphertext in polynomial time.

## 6 Practical Experiments

In appendix, we illustrate the attack against the original Augot and Finiasz' cryptosystem for small parameters. We have also implemented our attack using Shoup's NTL library [12]. The attack works well in practice. For the recommended parameters ( $n = 1024$ ,  $k = 900$ ,  $\omega = 25$ ,  $W = 74$ ,  $q = 2^{80}$ ), it takes roughly 30 minutes on a single PC to recover the plaintext from the ciphertext and the public-key. We have also implemented our attack against the repaired cryptosystem, and for the recommended parameters, it takes roughly 8 minutes on a single PC to recover the plaintext from the ciphertext and the public-key.

## 7 Discussion

In this section, we try to see if it is possible to modify the parameters of the scheme in order to resist to the previous attack. The only condition on the parameters for the attack to work is inequality (11). Therefore, one may try to increase  $k$ ,  $u$  or  $\omega$  while keeping  $n$  constant. In the following, we show that this is not possible. Namely, we describe another attack on the repaired cryptosystem that recovers the private-key from the public-key. The attack does not work for the recommended parameters, but applies for large  $u$ .

The attack is the following. Let  $K = ev(p) + E$  be the public-key with the  $n$  components  $K_i$ , where  $\deg p = k - 1$  and the weight of  $E$  is  $W$ . The Berlekamp-Welsh algorithm for recovering  $p$  from  $K$  is the following: it looks for two polynomials  $V$  and  $N$  such that  $\deg V = W$ ,  $\deg N = k + W - 1$  and  $V \neq 0$ , such that:

$$\forall i \in [1, n], V(x_i) \cdot K_i = N(x_i)$$

This gives a homogeneous linear system of  $n$  equations in  $k + 2 \cdot W + 1$  unknowns. This system has a non-zero solution as we can take  $V(X) = \prod_{i \in B} (X - x_i)$  with  $B = \{i | E_i \neq 0\}$  and  $N = p \cdot V$ . Letting  $V$ ,  $N$  be any non-zero solution, we have for at least  $n - W$  values of  $i$ :

$$V(x_i) \cdot p(x_i) = N(x_i)$$

Therefore, if  $n - W > k + W - 1$ , or equivalently,

$$n \geq k + 2 \cdot W \tag{12}$$

the polynomials  $V \cdot p$  and  $N$  must be equal, which enables to recover  $p$  as  $p = N/V$ .

As in the attack of section 5, from  $K$  we derive the  $u$  vectors  $K_t$  for  $t = 1, \dots, u$  such that:

$$K_t = \text{Tr}(\gamma_t \cdot K)$$

where  $\gamma_1, \dots, \gamma_u$  is a basis of  $\text{GF}(q^u)$  over  $\text{GF}(q)$ . Then we have:

$$K_t = \text{Tr}(\gamma_t \cdot (ev(p) + E)) = ev(\text{Tr}(\gamma_t \cdot p)) + \text{Tr}(\gamma_t \cdot E)$$

Letting  $p_t = \text{Tr}(\gamma_t \cdot p)$  and  $E_t = \text{Tr}(\gamma_t \cdot E)$ , we can write:

$$\forall t \in [1, u], K_t = ev(p_t) + E_t$$

Therefore, we obtain a set of  $u$  vectors  $K_t$  which are evaluation of a polynomial  $p_t$  plus some error  $E_t$ . Thus we obtain  $u$  instances of the polynomial reconstruction problem over  $\text{GF}(q)$ .

The key observation is that the instances are not independent because the errors occur in the same positions in all vectors  $E_t$ . This enables to derive the following improved attack: we look for a polynomial  $V \neq 0$ ,  $\deg V \leq W$  and polynomials  $N_1, \dots, N_u$ ,  $\deg N_t \leq k + W - 1$  such that:

$$\forall i \in [1, n], \begin{cases} V(x_i) \cdot K_{1,i} = N_1(x_i) \\ \dots \\ V(x_i) \cdot K_{u,i} = N_u(x_i) \end{cases}$$

We can take the same polynomial  $V$  for each  $t \in [1, u]$  because the errors are in the same positions for all  $E_t$ . This gives a system of  $u \cdot n$  equations in the  $u \cdot k + (u + 1) \cdot W + 1$  unknowns. Let  $M$  be the corresponding matrix. It has  $u \cdot n$  rows and  $u \cdot k + (u + 1) \cdot W + 1$  columns. We assume that:

$$u \cdot n \geq u \cdot k + (u + 1) \cdot W \quad (13)$$

The system has a non-zero solution. Therefore, the matrix cannot be of maximum rank, therefore  $\text{rank } M \leq u \cdot k + (u + 1) \cdot W$ . In the following, we assume that  $\text{rank } M = u \cdot k + (u + 1) \cdot W$ . This makes our attack heuristic, but the heuristic works well in practice. In this case, as in section 5, the kernel of  $M$  is a linear space of dimension one, and given a solution  $(V, N_1, \dots, N_u)$ , one can recover the polynomials  $p_t$  as  $p_t = N_t/V$  and then recover the private key  $(p, E)$ . A similar approach was already used in [4] for the decoding of interleaved Reed-Solomon codes.

The inequality (13) gives the following condition for the attack to work:

$$n \geq k + \frac{u + 1}{u} \cdot W$$

which is an improvement over (12). Note that for the recommended parameters in [2], the attack does not apply. Therefore, to prevent this attack, one must have:

$$n < k + \frac{u + 1}{u} \cdot W \quad (14)$$

Then, combining inequality (14) with inequality (7) which is necessary to be able to decrypt, one must have:

$$n \geq k + 2 \cdot (u + 1) \cdot \omega$$

which shows that condition (11) of the attack of section 5 is always satisfied. Therefore, there is no set of parameters which makes the repaired cryptosystem secure against both attacks.

## 8 Conclusion

We have broken the cryptosystem published by Augot and Finiasz at Eurocrypt 2003 and its reparation in [2]. In both cases, our attack recover the plaintext from the ciphertext and the public-key in polynomial time. Moreover, both attack work well in practice, as for the recommended parameters, one recovers the plaintext in a few minutes on a single PC.

## A A Toy Example

In this section we illustrate the attack for small parameters. We take  $n = 8$ ,  $k = 3$ ,  $\omega = 1$ ,  $W = 3$ . We work modulo  $q = 11$ . We take  $x_i = i$  for  $i = 1, \dots, 8$ . We take:

$$p(x) = x^2 + 5x + 3$$

$$E = (0, 0, 4, 0, 7, 6, 0, 0)$$

for the private key. The public-key is:

$$z = ev(p) + E = (9, 6, 9, 6, 5, 9, 10, 8)$$

Let the message  $m$  be  $m(x) = 8x + 2$ . Let  $\alpha = 7$  and  $e = (0, 5, 0, 0, 0, 0, 0, 0)$ . The ciphertext  $y$  is:

$$y = ev(m) + \alpha \times z + e = (7, 10, 1, 10, 0, 3, 7, 1)$$

The matrix  $M(\lambda)$  is then:

$$M(\lambda) = \begin{bmatrix} 7 - 9\lambda & 7 - 9\lambda & 10 & 10 & 10 & 10 \\ 10 - 6\lambda & 9 - \lambda & 10 & 9 & 7 & 3 \\ 1 - 9\lambda & 3 - 5\lambda & 10 & 8 & 2 & 6 \\ 10 - 6\lambda & 7 - 2\lambda & 10 & 7 & 6 & 2 \\ -5\lambda & -3\lambda & 10 & 6 & 8 & 7 \\ 3 - 9\lambda & 7 - 10\lambda & 10 & 5 & 8 & 4 \\ 7 - 10\lambda & 5 - 4\lambda & 10 & 4 & 6 & 9 \\ 1 - 8\lambda & 8 - 9\lambda & 10 & 3 & 2 & 5 \end{bmatrix}$$

The determinant  $f(\lambda)$  of the matrix  $M'(\lambda)$  obtained by taking the first 6 lines of  $M(\lambda)$  is equal to:

$$f(\lambda) = \det M'(\lambda) = 3\lambda^2 + 5\lambda + 5$$

which factors modulo  $q = 11$  into:

$$f(\lambda) = 3 \cdot (\lambda - 6) \cdot (\lambda - 7)$$

For  $\lambda = 7$ , the matrix  $M'(7)$  is non-invertible. We solve the linear system and find that  $Y = (8, 7, 5, 1, 1, 0)$  is such that  $M(7).Y = 0$ ; this gives  $V(x) = 7x + 8$  and  $N(x) = x^2 + x + 5$ , which gives modulo  $q = 11$ :

$$m(x) = N(x)/V(x) = 8x + 2$$
