Abstract. We introduce the first proof system for layered arithmetic circuits over an arbitrary ring R that is (possibly) non-commutative and (possibly) infinite, while only requiring black-box access to its arithmetic and a subset $A \subseteq R$. Our construction only requires limited commutativity and regularity properties from A, similar to recent work on efficient information theoretic multi-party computation over non-commutative rings by Escudero and Soria-Vazquez (*CRYPTO 2021*), but furthermore covering infinite rings.
We achieve our results through a generalization of GKR-style interactive proofs (Goldwasser, Kalai and Rothblum, *Journal of the ACM*, 2015). When A is a subset of the center of R, generalizations of the sum-check protocol and other building blocks are not too problematic. The case when the elements of A only commute with each other, on the other hand, introduces a series of challenges. In order to overcome those, we need to introduce a new definition of polynomial ring over a non-commutative ring, the notion of *left* (and *right*) multi-linear extensions, modify the layer consistency equation and adapt the sum-check protocol.
Despite these changes, our results are compatible with recent developments such as linear time provers. Moreover, for certain rings our construction achieves provers that run in *sublinear* time in the circuit size. We obtain such result both for known cases, such as matrix and polynomial rings, as well as new ones, such as for some rings resulting from Clifford algebras. Besides efficiency improvements in computation and/or round complexity for several instantiations, the core conclusion of our results is that state of the art doubly efficient interactive proofs do not require much algebraic structure. This enables *exact* rather than *approximate* computation over infinite rings as well as "agile" proof systems, where the black-box choice of the underlying ring can be easily switched through the software life cycle.

1 Introduction

Interactive proofs (IPs) are a natural extension of the standard notion of a mathematical proof, where the *verifier* checking a proof is allowed to interrogate the *prover* who is providing it. They were introduced by Goldwasser, Micali and Rackoff [GMR89] in the 1980s and they soon made a huge impact in complexity

theory. IPs have also been influential to practical proof systems, for which a lot of progress took place during the last decade. Usually, in those schemes, the prover tries to convince a verifier about the correctness of the evaluation of a circuit consisting of addition and multiplication gates. Moreover, the arithmetic of this circuit is often over a finite field, no matter how well represented under these constraints is the original computation whose correctness is being checked.

In 2008, Goldwasser, Kalai and Rothblum (GKR) presented the first *doubly-efficient* interactive proof [GKR15], where the prover is only required to perform a polynomial amount of work in the size of the (layered, over a finite field) arithmetic circuit and the verifier only needs to be quasi-linear in the same parameter. The prover's effort was later improved to quasi-linear [CMT12] and finally linear [XZZ+19] for the same family of circuits in 2019. Recently, the restriction to layered circuits was removed [ZLW+21] without affecting the linear complexity of the prover and only a slight increase in the verifier's work for non-layered circuits. In this work we are interested in a different kind of generalization of the GKR protocol. Namely, we set out to answer the following question:

> "Let C be a layered arithmetic circuit over a ring R. What algebraic properties does R need to satisfy in order to construct a doubly-efficient IP for C's correct evaluation, without emulating R's arithmetic?"

The most relevant part of our quest is that of avoiding the emulation of R's arithmetic, which we refer to as being *black-box* over R. We answer this question in a partial but constructive way by providing a doubly-efficient IP for rings R that are possibly *non-commutative* as well as *infinite*.

The *black-box* nature of our constructions has a theoretical interest, in the tradition of finding lower bounds and reducing assumptions. Namely, it helps us understand what are the *minimum* algebraic properties that need to be assumed for proof systems and their underlying techniques to go through, and how does this affect their complexity. Whereas this path has been more explored in the context of Multi-Party Computation (MPC, see e.g. [CFIK03, CDI+13, ACD+19, DLS20, ES21] just to name a few), it has been strangely overlooked in the context of proof and argument systems, with notable exceptions [AIK10, HR18, CCKP19, GNS21, BCFK21, BCS21]. The main take-away of our work is that, when it comes to GKR-style protocols and their complexity, the algebraic properties of the ring do not matter much as long as it contains a big enough *set* with "good enough" regular and commutative properties. Since infinite rings are allowed, this is a superset of the rings for which we know how to build efficient information-theoretic MPC in a black-box manner [ES21].

Besides the theoretical aspects of our work, we expect its generality to find applications in practice. Practically relevant infinite rings (such as the integers) and fields (such as rational or real numbers) as well as non-commutative rings (such as matrices and quaternions) did not fit previous systems. Their arithmetic had to be emulated (at best) or approximated (at worst) when compiled into circuits over either finite fields or finite commutative rings [CCKP19]. Avoiding this compilation step can bring improvements in several fronts. First of all, removing this stage simplifies the practitioners' work, who can now be *agile* with respect

to the choice of rings that are more commonplace than finite fields. If, after deployment, they need to provide a new proof system with a different underlying arithmetic, they could simply change the underlying data type that represents the ring, rather than having to develop an ad-hoc compiler. Moreover, working natively over such data types (algebraic structures) allows them to easily use existing software libraries for those, since their arithmetic does not need to be compiled into circuits. This, in turn, results in circuits with significantly less gates, which can ultimately result in better concrete efficiency in terms of computation and round complexity. Finally, the soundness error of our black-box IP can also benefit from working over these rings. We encourage to read specific applications and instantiations in the full version [Sor22].

Related work. In [AIK10] Applebaum, Ishai and Kushilevitz show how to construct a verifiable computation protocol out of message authentication codes (MACs) and randomized encodings (REs). For their construction to be a *proof* rather than an *argument* system, it would need to use information-theoretic MACs and statistically secure REs. It is a longstanding open problem whether such statistical REs could efficiently support layered arithmetic circuits over the non-commutative and infinite rings that we support, or even finite fields. In particular, such REs would imply efficient constant-round statistically secure multi-party computation protocols for such circuits, which in turn solves an open problem about locally decodable codes of quasi-polynomial parameters [IK04].

In 2013, Meir [Mei13] demonstrated how the **IP** = **PSPACE** result can be proven using error-correcting codes (ECCs) that are more general than low degree polynomials. Along the way, the sum-check protocol is generalized to work with tensor products of linear ECCs. While that work is also interested in reducing algebraic assumptions, the results and ECCs are defined over finite fields. Whereas Meir's goal is to provide a new proof for a complexity theory result, we want to expand the amount of rings that one can use in a black-box way for GKR-style protocols and we care about concrete efficiency.

1.1 Technical overview

The GKR protocol [GKR15] is a doubly-efficient interactive proof for the evaluation of a layered arithmetic circuit, which consists of addition and multiplication gates of fan-in two. Parties move from the output (0-th layer) to the input layer (D-th layer) one layer at a time. Each gate in the i-th layer is supposed to take inputs from two wires in layer $i+1$, and so the output wires of the i-th layer gates are checked to be consistent with the ones in the preceding layer. Let $V^{(i)} : \{0,1\}^{s_i} \to \mathbb{F}$ be the function that maps the string x to the value of the x-th wire in layer i. Thus, layer i has (up to) 2^{s_i} wires. Furthermore, let $\mathtt{add}^{(i+1)} : \{0,1\}^{s_i} \times \{0,1\}^{s_{i+1}} \times \{0,1\}^{s_{i+1}} \to \{0,1\}$ be the function satisfying $\mathtt{add}^{(i+1)}(z,x,y) = 1$ if the z-th wire on layer i is the addition of the x-th and y-th wires in layer $i+1$, otherwise $\mathtt{add}^{(i+1)}(z,x,y) = 0$. Define $\mathtt{mult}^{(i+1)}$ analogously. If we use $\hat{f} \in \mathbb{F}[\vec{\mathtt{X}}]$ to denote a (low degree) multivariate polynomial such

that for all $a \in \{0,1\}^s$, $\hat{f}(a) = f(a)$, we can express layer consistency as follows:

$$\hat{V}^{(i)}(\vec{\mathtt{Z}}) = \sum_{x,y \in \{0,1\}^{s_{i+1}}} \Big(\widehat{\mathtt{mult}}^{(i+1)}(\vec{\mathtt{Z}}, x, y) \cdot \big(\hat{V}^{(i+1)}(x) \cdot \hat{V}^{(i+1)}(y)\big) + \\ + \ \widehat{\mathtt{add}}^{(i+1)}(\vec{\mathtt{Z}}, x, y) \cdot \big(\hat{V}^{(i+1)}(x) + \hat{V}^{(i+1)}(y)\big) \Big). \quad (1)$$

The advantage of using the polynomial extensions $\hat{V}^{(i)}, \hat{V}^{(i+1)}, \widehat{\mathtt{mult}}^{(i+1)}$ and $\widehat{\mathtt{add}}^{(i+1)}$ is that the previous equation can be easily checked using the sum-check protocol [LFKN92]. Originally, as well as for most of its subsequent literature, the GKR protocol only worked for circuits over finite fields. Chen et al. [CCKP19] showed how to extend this result to finite commutative rings as long as the points used to define the polynomial extensions and the random challenges from the verifier belong to a set $A = \{a_1, \ldots, a_n\}$ where $\forall i \neq j, a_i - a_j$ is not a zero divisor. In our work, we denote such A a *regular difference* set.

As we realized, removing the finiteness assumption from [CCKP19] does not introduce any additional problems. Even if R is infinite, we only need a finite regular difference set A. On the other hand, when R is not commutative, we are presented with several issues. First, the definition of a polynomial ring with coefficients in R is not straightforward. One easily finds obstacles related to whether polynomial evaluation is a ring homomorphism (i.e., whether $f(a)+g(a) = (f+g)(a)$ and $f(a) \cdot g(a) = (f \cdot g)(a)$) or other crucial results, such as Euclidean division or bounding the number of roots of a polynomial. Nevertheless, if we restrict the regular difference set A to be contained in the center of the ring (i.e., $\forall r \in R, a \in A, a \cdot r = r \cdot a$), then Equation (1) (and multi-linear extensions, the sum-check protocol, etc.) behave as expected. In this scenario, which we discuss in Section 4, we use the most common definition for polynomial over non-commutative rings (Definition 9, the same as in [ES21]).

The most challenging part of our work comes from relaxing the commutativity requirement on A, so that rather than $A \subset Z(R)$, we only ask that $\forall a_i, a_j \in A, a_i \cdot a_j = a_j \cdot a_i$. This was also the most difficult family of rings in [ES21], where Escudero and Soria-Vazquez showed how to build efficient information-theoretic MPC protocols with black-box access to such a ring[1]. Employing the same polynomial ring definition as in [ES21] fails in our context. This poses the question of whether there are inherently more *algebraic* limitations for doubly-efficient IPs than there are for information theoretic MPC, potentially ruling out these "less commutative" rings. Fortunately, we overcome most problems by putting forward a new polynomial ring definition (Definition 12) in Section 3, the notion of *sandwich* (and *toast*) polynomials (Section 3.1) and reworking many basic algebraic results related to these new polynomials. We show that there is no unique notion of multi-linear extension (MLE) in this setting, so we have to define both *left* and *right* MLEs. Equipped with these results, in Section 5 we show how to modify the layer consistency equation so that it

[1] In fact, in [ES21] they only show how to work with *finite* rings in that family. An example interesting ring in this setting is $\mathcal{M}_{n\times n}(\mathbb{F}_2)$, which has $\mathbb{F}_{2^n}$ as a subfield.

becomes a sandwich polynomial. We need to do this carefully, so that it is a toast polynomial on every indeterminate. Finally, we provide a new sum-check protocol for this layer consistency equation (Section 5.3), which we show how the prover can run run in linear time in Section A.

2 Preliminaries

Notation. We use $[i, j]$, where $i < j$, to represent the set of positive integers $\{i, i+1, \ldots, j\}$, and simply $[n]$ to represent $\{1, 2, \ldots, n\}$. Sometimes, we may use arrows to denote vectors, e.g. $\vec{b} = (b_1, \ldots, b_n)$. For a "sub-interval" of the elements of a vector, we might denote use $\vec{b}_{[i,j]} = (b_i, \ldots, b_j)$.

2.1 Interactive proofs and the GKR protocol

In order to capture more naturally our results, we present these definitions in terms of the prover $\mathcal{P}$ trying to convince a verifier $\mathcal{V}$ that the application of an arithmetic circuit C over a ring R on some input $\texttt{inp}$ results on a specific output $\texttt{out}$, where inputs and outputs are elements of R.

Definition 1. *Let C be an arithmetic circuit over a ring R. A pair of interactive machines $\langle \mathcal{P}, \mathcal{V} \rangle$ is an ϵ-sound interactive proof (IP) for C if, on a claimed output $\texttt{out}$ by $\mathcal{P}$:*

- *Completeness: For every $\texttt{inp}$ s.t. $C(\texttt{inp}) = \texttt{out}$, it holds that $\Pr[\langle \mathcal{P}, \mathcal{V} \rangle(\texttt{inp}) = \texttt{accept}] = 1$.*
- *ϵ-Soundness: For any $\texttt{inp}$ s.t. $C(\texttt{inp}) \neq \texttt{out}$, and any $\mathcal{P}^*$, it holds that $\Pr[\langle \mathcal{P}^*, \mathcal{V} \rangle(\texttt{inp}) = \texttt{accept}] \leq \epsilon$.*

We say that an interactive proof has the succinct property if the running time of $\mathcal{V}$ and the total communication between $\mathcal{P}$ and $\mathcal{V}$ is $\mathsf{poly}(|x|, \log(|C|))$.

The sum-check protocol Given an n-variate polynomial $f : \mathbb{F}^n \to \mathbb{F}$, the sum-check protocol [LFKN92] allows a verifier to outsource the computation of $\sum_{\vec{b} \in \{0,1\}^n} f(\vec{b})$ to a prover. If the verifier was to do this on their own, it would take them $O(2^n)$ time. Let d be an upper bound on the degree of each individual variable of f. The sum-check protocol is an n-round interactive proof for this task, where both the proof size and the verifier's work is $O(n \cdot d)$ and the soundness error is $\epsilon = n \cdot d \cdot |\mathbb{F}|^{-1}$. For a full description see either [LFKN92] or the full version of this work.

The GKR protocol The basics of how circuits and wire values are represented in the GKR protocol have been explained at the beginning of Section 1.1. Here we give a bit more details about how Equation (1) is combined with the sum-check protocol and how to progress from the output to the input layer. $\mathcal{P}$ first sends the claimed output to $\mathcal{V}$, consisting of 2^{s_0} different values. $\mathcal{V}$ defines a multi-linear

polynomial $\hat{V}^{(0)} : \mathbb{F}^{s_0} \to \mathbb{F}^{s_0}$ which extends $V^{(0)}$, samples a random $\gamma \in \mathbb{F}^{s_0}$ and sends it to $\mathcal{P}$. Both parties then evaluate $\hat{V}^{(0)}(\gamma)$ and run a sum-check protocol on Eq. (1) for $i = 0$ and evaluated at γ. Let $f_i(\vec{\mathsf{Z}}, \vec{\mathsf{X}}, \vec{\mathsf{Y}})$ be the function such that Eq. (1) is $\hat{V}^{(i)}(\vec{\mathsf{Z}}) = \sum_{x,y \in \{0,1\}^{s_{i+1}}} f_i(\vec{\mathsf{Z}}, x, y)$. At the end of the protocol, $\mathcal{V}$ needs to compute $f_0(\gamma, \chi, \psi)$, where $\chi, \psi \in \mathbb{F}^{s_1}$ are two random values produced throughout the sum-check execution. Whereas $\mathcal{V}$ can evaluate $\widehat{\mathtt{add}}^{(1)}(\gamma, \chi, \psi)$ and $\widehat{\mathtt{mult}}^{(1)}(\gamma, \chi, \psi)$ on their own, it has to ask $\mathcal{P}$ for $\hat{V}^{(1)}(\chi), \hat{V}^{(1)}(\psi)$, since those evaluations require the knowledge of the wire values on layer 1. This way, a claim about the output layer has been reduced to two claims about layer one, $\hat{V}^{(1)}(\chi)$ and $\hat{V}^{(1)}(\psi)$. $\mathcal{V}$ and $\mathcal{P}$ could run one sum-check protocol for each of those claims using Eq. (1) for $i = 1$, but the number of sum-check executions would eventually become exponential in the depth of the circuit by following such a route. In order to avoid this, both claims are combined into a single claim. We provide a full description of the GKR protocol in the full version [Sor22]. Below, we state the complexity and soundness of its current most efficient version.

Theorem 1 ([XZZ+19]). *Let $C : \mathbb{F}^n \to \mathbb{F}^k$ be a depth-D layered arithmetic circuit. The GKR protocol is an interactive proof for C with soundness error $O(D \log |C|/|\mathbb{F}|)$. Its communication and round complexity is $O(D \log |C|)$. The prover complexity is $O(|C|)$ and the verifier complexity is $O(n+k+D \log |C|+T)$, where T is the optimal time to evaluate every $\widehat{\mathtt{add}}^{(i)}, \widehat{\mathtt{mult}}^{(i)}$ wiring predicate. For log-space uniform circuits, $T = \mathsf{poly} \log(|C|)$.*

2.2 Algebraic background

We recap some basic notions in non-commutative algebra. Unless otherwise specified, whenever we talk about a ring R we mean a ring with identity $1 \neq 0$, for which we assume neither commutativity nor finiteness.

Definition 2. *Let R be a ring. An element $a \in R$ is a unit if there exists $b \in R$ such that $a \cdot b = b \cdot a = 1$. The set of all units is denoted by R^*.*

Definition 3. *An element $a \in R \setminus \{0\}$ is a left (resp. right) zero divisor if $\exists\ b \in R \setminus \{0\}$ such that $a \cdot b = 0$ (resp. $b \cdot a = 0$).*

Sets of elements whose pairwise differences are either regular or invertible will play a crucial role in our constructions.

Definition 4. *Let $A = \{a_1, \ldots, a_n\} \subset R$. We say that A is a regular difference set, or R.D. set for short, if $\forall i \neq j, a_i - a_j \in R$ is not a zero divisor. We define the* regularity constant *of R to be the maximum size of an R.D. set in R.*

Definition 5. *Let $A = \{a_1, \ldots, a_n\} \subset R$. We say that A is an exceptional set if $\forall i \neq j, a_i - a_j \in R^*$. We define the* Lenstra constant *of R to be the maximum size of an exceptional set in R.*

Besides "how regular" or "how invertible" are certain subsets of ring elements, we might also be interested in "how commutative" they are.

Definition 6. *The center of a ring R, denoted by $Z(R)$ consists of the elements $a \in Z(R)$ such that $\forall b \in R$, $a \cdot b = b \cdot a$.*

Definition 7 ([QBC13]). *Let $A = \{a_1, \ldots, a_n\} \subset R$. We say that A is a commutative set if $\forall a_i, a_j \in A, a_i \cdot a_j = a_j \cdot a_i$.*

Definition 8. *Let R be a ring and $A \subset R$. The centralizer of the set A in R is:*

$$C_R(A) = \{b \in R : b \cdot a = a \cdot b, \forall a \in A\}.$$

Lemma 1. *Let R be a ring and $A \subset R$ a commutative set. Then $C_R(A) \supseteq (A \cup Z(R))$. Furthermore, if $A \subseteq Z(R)$, then $C_R(A) = R$.*

3 Polynomials over non-commutative rings

There is no unique choice for how to define a polynomial ring with coefficients on a non-commutative ring R. Usually, as in [QBC13, ES21], univariate polynomials are defined in such a way that "the indeterminate commutes with coefficients", so as to *uniquely* express any polynomial $f \in R[\mathtt{X}]_{\leq d}$ as $f(\mathtt{X}) = \sum_{i=0}^{d} f_i \mathtt{X}^i$, where $f_i \in R$. In the language of centralizers, this approach enforces $C_{R[\mathtt{X}]}(\{\mathtt{X}\}) = R[\mathtt{X}]$. In the multivariate case, one can choose whether to define the ring so that indeterminates commute with each other or not. For rings where $A \subseteq Z(R)$, we will stick with the former case and refer to it as a *ring of non-commutative polynomials*. Due to space constraints, we defer the proofs of every statement in this section to the full version [Sor22].

Definition 9. *Let $(R, +, *)$ be a ring and let $\Sigma = \{\mathtt{X}_1, \ldots, \mathtt{X}_n\}$. Let Σ^* be the free commutative monoid generated by Σ, i.e. the monoid whose binary operation is the concatenation of finite strings and the letters of the alphabet Σ commute with each other. The* ring of non-commutative polynomials *$R[\mathtt{X}_1, \ldots, \mathtt{X}_n]$ is the monoid ring of Σ^* over R. Explicitly, $a \in R[\mathtt{X}_1, \ldots, \mathtt{X}_n]$ is of the form $a = \sum_{m \in \Sigma^*} a_m m$, where $a_m \in R$ and there is only a finite amount of $a_m \neq 0$. Addition and multiplication are defined as follows:*

- *Addition: $a + b = \sum_{m \in \Sigma^*} (a_m + b_m) m$*
- *Multiplication: $a \cdot b = \sum_{m_1, m_2 \in \Sigma^*} (a_{m_1} \cdot b_{m_2}) m_1 m_2$.*

Furthermore, for any set $S \subseteq R$, we define $S[\mathtt{X}_1, \ldots, \mathtt{X}_n]_{\leq d}$ to be the subset of polynomials in $R[\mathtt{X}_1, \ldots, \mathtt{X}_n]$ of degree at most d whose coefficients belong to S.

The previous definition has many advantages, but it requires to be careful about polynomial evaluation, which we next show to be a ring homomorphism if and only if the evaluation points belong to $Z(R)$. For example, consider polynomials $f(\mathtt{X}) = f_0 + f_1\mathtt{X}$ and $g(\mathtt{X}) = g_1\mathtt{X} + g_2\mathtt{X}^2$. We would have that $h(\mathtt{X}) = f(\mathtt{X}) \cdot g(\mathtt{X}) = f_0 g_1 \mathtt{X} + (f_0 g_2 + f_1 g_1)\mathtt{X}^2 + f_1 g_2 \mathtt{X}^3$. Unless α commutes with g_1 and g_2, this results in $h(\alpha) \neq f(\alpha) \cdot g(\alpha)$.

Lemma 2. *Let $A = \{\alpha_i\}_{i=1}^n \subset R$ be a commutative set and let $\alpha = (\alpha_1, \ldots, \alpha_n)$. Denote by $\texttt{Ev}_\alpha : R[\texttt{X}_1, \ldots, \texttt{X}_n] \to R$ the map that takes a polynomial $f \in R[\texttt{X}_1, \ldots, \texttt{X}_n]$ to its evaluation[2] at α, by replacing each appearance of $\texttt{X}_i$ with α_i and applying the product operation of R. Then:*

1. $\forall f, g \in R[\texttt{X}_1, \ldots, \texttt{X}_n]$, $\texttt{Ev}_\alpha(f) + \texttt{Ev}_\alpha(g) = \texttt{Ev}_\alpha(f + g)$.
2. $\texttt{Ev}_\alpha(f) \cdot \texttt{Ev}_\alpha(g) = \texttt{Ev}_\alpha(f \cdot g)$ *holds* $\forall f, g \in R[\texttt{X}_1, \ldots, \texttt{X}_n]$ *if and only if* $A \subseteq Z(R)$.

A different way to define the polynomial ring is by treating the indeterminate $\texttt{X}$ as a formal, non-commuting symbol. Polynomial addition works as usual, whereas the product looks similar to string concatenation. In terms of centralizers, in this approach we enforce $C_{R[\texttt{X}]}(\{\texttt{X}\}) = \emptyset$. The advantage of this strategy is that polynomial evaluation at any $\alpha \in R$ becomes a ring homomorphism, in contrast with Definition 9, where that is only true if $\alpha \in Z(R)$ (Lemma 2). On the other hand, not being able to simplify polynomial expressions as in Definition 9 not only results in lengthier polynomials, but it also eliminates the possibility to prove many useful results about polynomials. We will refer to this construction as the *ring of totally non-commutative polynomials*.

Definition 10. *Let $(R, +, \odot)$ be a ring and let $\Sigma = R \cup \{\texttt{X}_1, \ldots, \texttt{X}_n\}$. Let $*$ denote the string concatenation operation. Let $\mathbf{M}$ be the monoid generated by Σ according to the non-commutative binary operation $\cdot : \mathbf{M} \times \mathbf{M} \to \mathbf{M}$, which we restrict to finite strings and where:*

$$r \cdot s = \begin{cases} r \odot s, & \text{if } r, s \in R \\ r * s, & \text{if } (r \in R \wedge s \in \{\texttt{X}_i\}_{i=1}^n) \vee (r \in \{\texttt{X}_i\}_{i=1}^n \wedge s \in R) \vee (r, s \in \{\texttt{X}_i\}_{i=1}^n) \end{cases} \tag{2}$$

The ring of totally non-commutative polynomials *$R[\![\texttt{X}_1, \ldots, \texttt{X}_n]\!]$ consists of elements $a \in R[\![\texttt{X}_1, \ldots, \texttt{X}_n]\!]$ of the form $a = \sum_{m \in \mathbf{M}} a_m \cdot m$, where $a_m \in R$ and there is only a finite amount of $a_m \neq 0$. Addition (inherited from R) and multiplication (inherited from $\mathbf{M}$) are defined as follows:*

- *Addition:* $a + b = \sum_{m \in \mathbf{M}} (a_m + b_m) \cdot m$
- *Multiplication:* $a \cdot b = \sum_{m_1, m_2 \in \mathbf{M}} a_{m_1} \cdot m_1 \cdot b_{m_2} \cdot m_2$.

Lemma 3. *$R[\![\texttt{X}_1, \ldots, \texttt{X}_n]\!]$ is a ring.*

Note 1. The only difference between $(\mathbf{M}, \cdot)$ in Definition 10 and the free monoid over Σ is that, in $\mathbf{M}$, strings containing sub-strings of the form $\texttt{X}_i * a * b * \texttt{X}_j$ do not exist, since in $\mathbf{M}$ those are "simplified" to $\texttt{X}_i * c * \texttt{X}_j$ where $c = a \odot b$.

Note 2. $R[\![\texttt{X}_1, \ldots, \texttt{X}_n]\!]$ allows for limited simplifications in polynomial expressions: Those inherited from the associative and distributive properties if we go from the "outside" to the "inside" of a monomial. E.g., it is true that

[2] Throughout the text, we implicitly refer to $\texttt{Ev}_\alpha(f)$ whenever we write either $f(\alpha)$ or $f(\alpha_1, \ldots, \alpha_n)$ and $f \in R[\texttt{X}_1, \ldots, \texttt{X}_n]$.

$\mathtt{X}r\mathtt{X}^3 + \mathtt{X}s\mathtt{X}^3 = \mathtt{X}(r+s)\mathtt{X}^3$, but $\forall m_1 \neq m_2 \in \mathbf{M}$, we cannot simplify beyond $\mathtt{X}r\mathtt{X}^3 m_1 + \mathtt{X}s\mathtt{X}^3 m_2 = \mathtt{X}(r\mathtt{X}^3 m_1 + s\mathtt{X}^3 m_2)$, since $m_1 \neq m_2$ "blocks" any simplification from the right end (besides any common factor at the right end of m_1, m_2).

The rationale behind defining the ring of non-commutative polynomials as in Definition 9, as they do in e.g. [QBC13, ES21], is that in those works unique polynomial interpolation is the most crucial property. In our case, the most important requirement is that polynomial evaluation is a ring homomorphism, so that we can meaningfully apply a sumcheck protocol to the layer consistency Equation (1). Unfortunately, the approach from Definition 10, where $C_{R[\mathtt{X}]}(\mathtt{X}) = \emptyset$, does not serve us either, since the layer consistency equation is *cubic*. As it will become clearer later on, when proving results about Euclidean division (Theorem 2) and Lemma 6, we cannot bound the number of roots of the product of three polynomials by simply following that route. Such bound is in turn necessary to establish the soundness error of our new interactive proofs.

Due to the above, we introduce a novel polynomial ring definition, somewhere between Definitions 9 and 10. We define the *polynomial ring with evaluation set* A, $R_A[\mathtt{X}]$, by taking into account the specific set of points $A \subset R$ on which polynomials will be ever evaluated. Rather than constructing the ring so that $C_{R[\mathtt{X}_1,\ldots,\mathtt{X}_n]}(\{\mathtt{X}_i\}_{i=1}^n) = R[\mathtt{X}_1,\ldots,\mathtt{X}_n]$ (as in Defn. 9) or such that $C_{R[\![\mathtt{X}_1,\ldots,\mathtt{X}_n]\!]}(\{\mathtt{X}_i\}_{i=1}^n) = \emptyset$ (as in Defn. 10), we will enforce $C_{R_A[\mathtt{X}_1,\ldots,\mathtt{X}_n]}(\{\mathtt{X}_i\}_{i=1}^n) = C_R(A) \cup \{\mathtt{X}_i\}_{i=1}^n$. Hence, in $R_A[\mathtt{X}_1,\ldots,\mathtt{X}_n]$, indeterminates commute with each other and "an indeterminate commutes with a coefficient $c \in R$ if and only if $c \in C_R(A)$". Formally, we construct $R_A[\mathtt{X}_1,\ldots,\mathtt{X}_n]$ by taking the quotient of the ring of totally non-commutative polynomials $R[\![\mathtt{X}_1,\ldots,\mathtt{X}_n]\!]$ with a "commutator ideal" I_A that enforces our precise commutativity requirements.

Definition 11. *Let $R[\![\mathtt{X}_1,\ldots,\mathtt{X}_n]\!]$ and let $A \subset R$. For $i,j = 1,\ldots n$, let $S_{i,j} = \{\mathtt{X}_i\mathtt{X}_j - \mathtt{X}_j\mathtt{X}_i\}$ and $S_i = \{\mathtt{X}_i c - c\mathtt{X}_i : c \in C_R(A)\}$. The two-sided ideal generated by $\bigcup_{i=1}^n \bigcup_{j=1}^{i-1} S_{i,j} \cup S_i$ is the* commutator ideal of A, *which we denote by I_A.*

For our specific goals, we will impose that the set A is commutative (see Definition 7). This is to ensure that $C_R(A) \supseteq (A \cup Z(R))$.

Definition 12. *Let $A \subset R$ be a commutative set and let I_A be the commutator ideal it defines. We define the* ring of polynomials with evaluation set A *to be $R_A[\mathtt{X}_1,\ldots,\mathtt{X}_n] = R[\![\mathtt{X}_1,\ldots,\mathtt{X}_n]\!]/I_A$. For any set $S \subseteq R$, we define $S_A[\mathtt{X}_1,\ldots,\mathtt{X}_n]$ to be the subset of polynomials in $R_A[\mathtt{X}_1,\ldots,\mathtt{X}_n]$ whose coefficients belong to S.*

Claim. Let $S \subseteq R$. Any $f \in S_A[\mathtt{X}_1,\ldots,\mathtt{X}_n]$ can be uniquely expressed as

$$f = \sum_{k=1}^{s} \Big(\prod_{\ell=1}^{m} \big(r_{k,\ell} \prod_{i=1}^{n} (\mathtt{X}_i^{d_{i,\ell}})\big)\Big),$$

where $r_{k,\ell} \in S \cup \{1\}, d_{i,\ell} \in \mathbb{Z}$ and m is the maximum length of any monomial in f. We consider $\mathtt{X}_i^0$ to be the empty string, for any $i = 1,\ldots,n$.

By Lemma 1, when $A \subseteq Z(R)$ we have that $C_R(A) = R$, in which case the commutator ideal enforces $C_{R_A[\mathtt{X}_1,\ldots,\mathtt{X}_n]}(\{\mathtt{X}_i\}_{i=1}^n) = R_A[\mathtt{X}_1,\ldots,\mathtt{X}_n]$. Intuitively, in this situation, the polynomial ring $R_A[\mathtt{X}_1,\ldots,\mathtt{X}_n]$ behaves *the same way* as $R[\mathtt{X}_1,\ldots,\mathtt{X}_n]$ in Definition 9: $R[\mathtt{X}_1,\ldots,\mathtt{X}_n]$ also satisfies that $C_{R[\mathtt{X}_1,\ldots,\mathtt{X}_n]}(\{\mathtt{X}_i\}_{i=1}^n) = R[\mathtt{X}_1,\ldots,\mathtt{X}_n]$ and, when the evaluation points are in $A \subseteq Z(R)$, evaluating polynomials from $R[\mathtt{X}_1,\ldots,\mathtt{X}_n]$ is a ring homomorphism too (Lemma 2). In the full version [Sor22] we show in more detail how both definitions are interchangeable for our purposes when $A \subseteq Z(R)$.

For the sake of generality, we will state and prove our results using the more general ring $R_A[\mathtt{X}_1,\ldots,\mathtt{X}_n]$ from Definition 12. Nevertheless, when $A \subset Z(R)$, it is conceptually simpler to treat polynomials as elements from $R[\mathtt{X}_1,\ldots,\mathtt{X}_n]$ (Definition 9). For basic algebraic results that we will present in Section 3.1, such as Euclidean division or the number of roots of a polynomial, simplified statements and proofs for $R[\mathtt{X}_1,\ldots,\mathtt{X}_n]$ can be found in e.g. [ES21].

3.1 Sandwich polynomials

In the previous block of results, we have seen that when $A \subset Z(R)$, the ring $R_A[\mathtt{X}_1,\ldots,\mathtt{X}_n]$ from Definition 12 behaves *the same way* as $R[\mathtt{X}_1,\ldots,\mathtt{X}_n]$ in Definition 9. It is when A is merely a commutative set –and hence $C_{R_A[\mathtt{X}_1,\ldots,\mathtt{X}_n]}(\mathtt{X}_i) \supseteq (A \cup Z(R) \cup \{\mathtt{X}_j\}_{j=1}^n)$– that our new Definition 12 will be necessary to enable our GKR-style protocol over a ring $R \supset A$.

Our protocols will be concerned with a particular *subset* of the polynomials in $R_A[\mathtt{X}_1,\ldots,\mathtt{X}_n]$, concretely the ones for which monomials have a single coefficient, possibly "surrounded" by indeterminates on both sides. We will refer to these as *sandwich polynomials*, metaphorically thinking of the indeterminates as bread and the coefficient as the content[3]. The goal of this subsection is to generalize the Schwartz-Zippel lemma to these polynomials, to the extent that it is possible.

Definition 13 (Sandwich polynomials). *Let A be a commutative subset of a ring R and let $R_A[\mathtt{X}_1,\ldots,\mathtt{X}_n]$ be the ring of polynomials with evaluation set A. Let $i = (i_1,\ldots,i_n)$, $j = (j_1,\ldots,j_n)$. We define the set of* sandwich polynomials *over R with left-degree at most d' and right-degree at most d to be:*

$$R_A[\mathtt{X}_1,\ldots,\mathtt{X}_n]_{\leq d',\leq d} = \{f(\mathtt{X}_1,\ldots,\mathtt{X}_n) = \sum_{i\in[0,d']^n, j\in[0,d]^n} \mathtt{X}_n^{i_n}\cdot\ldots\cdot\mathtt{X}_1^{i_1} f_{i,j} \mathtt{X}_1^{j_1}\cdot\ldots\cdot\mathtt{X}_n^{j_n} \mid f_{i,j}\in R\}$$

The subset of polynomials with right-degree exactly *d, $R_A[\mathtt{X}_1,\ldots,\mathtt{X}_n]_{\leq d',d} \subset R_A[\mathtt{X}_1,\ldots,\mathtt{X}_n]_{\leq d',\leq d}$, is given by further imposing that, for every $\mathtt{X}_k$, the polynomial must have at least one monomial of right-degree d in $\mathtt{X}_k$. Formally: $\forall k \in [n]$ $\exists i \in [0,d']^n, j_1,\ldots,j_{k-1},j_{k+1},\ldots,j_n \in [0,d]$ such that $f_{i,(j_1,\ldots,j_{k-1},d,j_{k+1},\ldots,j_n)} \neq 0$. The subset of polynomials with left-degree* exactly *d', $R_A[\mathtt{X}_1,\ldots,\mathtt{X}_n]_{d',\leq d}$, is*

[3] The reader might find funny to think about multiplication as "stacking sandwiches" and addition as putting sandwiches next to each other. The commutativity of indeterminates with elements in $C_R(A)$, simplifications enabled by the distributive property and other results in this section provide some (metaphorical) food for thought!

defined analogously. Furthermore, for any set $S \subseteq R$, we define $S_A[\mathtt{X}_1, \ldots, \mathtt{X}_n]_{\leq d', \leq d}$ as the subset of polynomials in $R_A[\mathtt{X}_1, \ldots, \mathtt{X}_n]_{\leq d', \leq d}$ whose coefficients $f_{i,j}$ all belong to S. Polynomials of exact degrees are defined as in the previous paragraph.

Definition 14 (Toast polynomials). *Let $\vec{\mathtt{X}} = (\mathtt{X}_1, \ldots, \mathtt{X}_n)$. A sandwich polynomial f is a* left *(resp.* right*)* toast polynomial *if it is of right (resp. left) degree zero, i.e. $f \in R_A[\vec{\mathtt{X}}]_{\leq d', 0}$ (resp. $f \in R_A[\vec{\mathtt{X}}]_{0, \leq d}$). If we do not want to specify the position of the indeterminate, we may simply refer to it as a* toast polynomial*.*

In the previous definitions, it is important to note that a polynomial in $R_A[\mathtt{X}_1, \ldots, \mathtt{X}_n]_{\leq d', \leq d}$ has at most $((d'+1) \cdot (d+1))^n$ monomials, i.e. for fixed powers $i \in [0, d']^n, j \in [0, d]^n$, an expression of the form $\sum_\ell \mathtt{X}_n^{i_n} \cdot \ldots \cdot \mathtt{X}_1^{i_1} f_{i,j}^{(\ell)} \mathtt{X}_1^{j_1} \cdot \ldots \cdot \mathtt{X}_n^{j_n}$ is simplified into $\mathtt{X}_n^{i_n} \cdot \ldots \cdot \mathtt{X}_1^{i_1} f_{i,j} \mathtt{X}_1^{j_1} \cdot \ldots \cdot \mathtt{X}_n^{j_n}$, where $f_{i,j} = \sum_\ell f_{i,j}^{(\ell)}$. Furthermore, when we talk about polynomials of *exact* right degree d or left degree d', we assume that all possible simplifications have taken place. In particular[4], for $f \in R_A[\mathtt{X}]_{\leq d', d}$, we assume that $f_{i,d}$ is not simplified away with terms of the form $\mathtt{X}^{i+k} f_{i+k,d-k} \mathtt{X}^{d-k}$, where $k \in \{1, \ldots, d\}$, when $f_{i,d}, f_{i+k,d-k} \in C_R(A)$.

Lemma 4. *Let $\vec{\mathtt{X}} = (\mathtt{X}_1, \ldots, \mathtt{X}_n)$. For $\ell = 1, \ldots m$, let $f^{(\ell)} \in R_A[\vec{\mathtt{X}}]_{\leq d'_f, \leq d_f}$, $a^{(\ell)} \in C_R(A)[\vec{\mathtt{X}}]_{\leq d'_a, \leq d_a}$ and $b^{(\ell)} \in C_R(A)[\vec{\mathtt{X}}]_{\leq d'_b, \leq d_b}$. Let $g = \sum_{\ell=1}^m a^{(\ell)} f^{(\ell)} b^{(\ell)}$. Then $g \in R_A[\vec{\mathtt{X}}]_{\leq (d'_a + d_a + d'_f), \leq (d'_b + d_b + d_f)}$.*

Lemma 5. *Let $f \in R_A[\mathtt{X}_1, \ldots, \mathtt{X}_n]_{\leq d', \leq d}$ and let $a_\ell \in A$. Then, $\forall \ell \in \{1, \ldots, n\}$:*

$$f(\mathtt{X}_1, \ldots \mathtt{X}_{\ell-1}, a_\ell, \mathtt{X}_{\ell+1}, \ldots, \mathtt{X}_n) \in R_A[\mathtt{X}_1, \ldots \mathtt{X}_{\ell-1}, \mathtt{X}_{\ell+1}, \ldots, \mathtt{X}_n]_{\leq d', \leq d}.$$

The advantage of sandwich polynomials is that they can be divided by monic polynomials in $S_A[\mathtt{X}]$, where $S = C_R(A)$ (recall notation from Definition 12).

Theorem 2 (Euclidean division). *Let $f(\mathtt{X}) \in R_A[\mathtt{X}]_{d', d}$ be a non-zero sandwich polynomial and let $g(\mathtt{X}) \in C_R(A)_A[\mathtt{X}]_{0,m}$ be a monic polynomial[5]. There exist unique sandwich polynomials $q_\ell(\mathtt{X}), r_\ell(\mathtt{X})$ (resp. $q_r(\mathtt{X}), r_r(\mathtt{X})$) such that $f(\mathtt{X}) = q_\ell(\mathtt{X}) \cdot g(\mathtt{X}) + r_\ell(\mathtt{X})$ (resp. $f(\mathtt{X}) = g(\mathtt{X}) \cdot q_r(\mathtt{X}) + r_r(\mathtt{X})$), where $q_\ell(\mathtt{X}) \in R_A[\mathtt{X}]_{\leq d', \leq d-m}$ and $r_\ell(\mathtt{X}) \in R_A[\mathtt{X}]_{\leq d', \leq m-1}$ (resp. $q_r(\mathtt{X}) \in R_A[\mathtt{X}]_{\leq d-m, \leq d}$, $r_r(\mathtt{X}) \in R_A[\mathtt{X}]_{\leq m-1, \leq d}$).*

Given the previous theorem, we can prove the following result about the maximum number of roots of toast polynomials on their evaluation set A, when A is not only commutative but also regular difference (Definition 4).

Lemma 6. *Let A be a commutative, regular difference set of R and let $f \in R_A[\mathtt{X}]_{0, \leq d}$ (resp. $\tilde{f} \in R_A[\mathtt{X}]_{\leq d, 0}$) be a non-zero toast polynomial. Then f (resp. $\tilde{f}$) has at most d roots in A.*

[4] We give this example in the univariate case in order to avoid heavier notation.

[5] I.e. $g(\mathtt{X}) = \mathtt{X}^m + \sum_{\ell=0}^{m-1} g_\ell \mathtt{X}^\ell$. Note that since $g_\ell \in C_R(A)$ $\forall \ell \in [0, m-1]$, it is also true that $g(\mathtt{X}) \in C_R(A)_A[\mathtt{X}]_{m,0}$, that $g(\mathtt{X}) \in C_R(A)_A[\mathtt{X}]_{m-1,1}$, etc.

The proof of the previous is particularly useful to understand our need for *toast* polynomials. Whereas, given Theorem 2 and Lemma 6, one could hope to be able to bound the number of roots of any polynomial $f \in R_A[\mathtt{X}]_{\leq d',\leq d}$, we were unable to prove such a result. This is due to the fact that the Euclidean division of sandwich polynomials by a polynomial $g_i(\mathtt{X}) = (X - \alpha_i)$, where α_i is a root of f, provides us with a remainder that is of degree zero *only on the side from which* $g_i(\mathtt{X})$ *is dividing*. If α_1 is a root of f, by calling Theorem 2 so that $g_1(\mathtt{X})$ "divides on the right", we can prove that $f(\mathtt{X}) = f_1(\mathtt{X})(\mathtt{X} - \alpha_1) + r_1(\mathtt{X})$, where $f_1 \in R_A[\mathtt{X}]_{\leq d',\leq d-1}, r_1 \in R_A[\mathtt{X}]_{\leq d',0}$. If we divide $r_1(\mathtt{X})$ by $g_1(\mathtt{X})$ on the left, we get to $f(\mathtt{X}) = f_1(\mathtt{X})(\mathtt{X}-\alpha_1)+(\mathtt{X}-\alpha_1)f_2(\mathtt{X})$, where $f_2 \in R_A[\mathtt{X}]_{\leq d'-1,0}$. The problem now is that, if $\alpha_2 \in A$ is another root, we find no way forward from the expression $0 = f(\alpha_2) = f_1(\alpha_2)(\alpha_2-\alpha_1)+(\alpha_2-\alpha_1)f_2(\alpha_2)$. Alternative strategies also beared no positive results. This important limitation will condition the generalization of almost every building block of our doubly-efficient IP over non-commutative rings when A is merely commutative, rather than $A \subseteq Z(R)$.

Lemma 7 generalizes the Schwartz-Zippel lemma to *toast* polynomials.

Lemma 7 (Schwartz-Zippel Lemma). *Let $A \subseteq R$ be a finite, commutative regular difference set. Let $\vec{\mathtt{X}} = (\mathtt{X}_1, \ldots, \mathtt{X}_n)$ and let $f \in (R_A[\vec{\mathtt{X}}]_{\leq d,0} \cup R_A[\vec{\mathtt{X}}]_{0,\leq d})$ be a non-zero toast polynomial. Then, $\Pr_{\vec{a} \leftarrow A^n}[f(\vec{a}) = 0] \leq n \cdot d \cdot |A|^{-1}$.*

Multi-linear extensions were introduced in [BFL91] and extensively used in [CMT12]. Here, we generalize their definition to toast polynomials (Defn. 14).

Lemma 8. *Let A be a regular difference, commutative set s.t. $\{0,1\} \subset A \subset R$. Given a function $V : \{0,1\}^m \to R$, there exist unique multilinear polynomials $\hat{V}_L \in R_A[\mathtt{X}_1, \ldots, \mathtt{X}_m]_{\leq 1,0}$ and $\hat{V}_R \in R_A[\mathtt{X}_1, \ldots, \mathtt{X}_m]_{0,\leq 1}$ extending V, i.e. $\hat{V}_L(a) = V(a) = \hat{V}_R(a)$ for all $a \in \{0,1\}^m$. We call $\hat{V}_L$ (resp. $\hat{V}_R$) the left (resp. right) multilinear extension of V, which we will abbreviate by LMLE (resp. RMLE).*

When $A \subset Z(R)$, or when $V : \{0,1\}^m \to C_R(A)$, it furthermore holds that $\hat{V}_L(\mathtt{X}_1, \ldots, \mathtt{X}_m) = \hat{V}_R(\mathtt{X}_1, \ldots, \mathtt{X}_m)$, in which case we will simply refer to the multilinear extension (MLE) of V and denote it by $\hat{V}(\mathtt{X}_1, \ldots, \mathtt{X}_m)$.

4 Doubly-efficient IP over non-commutative rings: Regular difference set contained in $Z(R)$

In our first generalization, we assume that A is an R.D. set such that $A \subset Z(R)$. This greatly simplifies our protocol compared with the one we will present in Section 5, where we only assume that A is commutative.

As most building blocks work essentially as in the finite commutative ring case [CCKP19], we only give a high level overview of this simpler variant. Since $A \subset Z(R)$, all polynomials can be expressed as elements from $R[\mathtt{X}_1, \ldots, \mathtt{X}_n]$ (the ring in Definition 9) rather than $R_A[\mathtt{X}_1, \ldots, \mathtt{X}_n]$ (as we show in the full version). This simpler polynomial ring definition is good enough in this case, since polynomial evaluation at elements in A is a ring homomorphism (Lemma 2) and furthermore we can bound the number of roots of these polynomials in A. The

latter has been proved in [QBC13, ES21], where they use exceptional rather than R.D. sets, but such assumption can be weakened for that result. Furthemore, we have unique MLEs rather than LMLEs and RMLEs (see Lemma 8) and both the layer consistency equation (Eq. (1)) and sum-check protocol generalize naturally.

The only state-of-the-art tool for doubly-efficient IPs that requires more care in this scenario is the linear time prover sum-check protocol from [XZZ+19]. This is a problem which we also encounter and solve in the harder case of Section 5. We refer the reader interested in the particularities of this case to the full version.

Theorem 3. *Let R be a ring and $A \subset Z(R)$ a regular difference set. Let $C : R^n \to R^k$ be a depth-D layered arithmetic circuit. There is an interactive proof for C with soundness error $O(D \log |C|/|A|)$. Its round complexity is $O(D \log |C|)$ and it communicates $O(D \log |C|)$ elements in R. The prover complexity is $O(|C|)$ and the verifier complexity is $O(n + k + D \log |C| + T)$, where T is the optimal time to evaluate every wiring predicate. For log-space uniform circuits, $T = \mathsf{poly} \log(|C|)$ and hence the IP is succinct.*

4.1 Improved efficiency

The generality of our construction opens up possibilities for concrete efficiency improvements. One such example is the case when the ring R over which the circuit is defined can be seen as a free module of rank d over a ring S with a R.D. set $A \subseteq Z(S)$. Namely, as long as a product of elements in R takes more than d products in S, we have achieved our goal: Once the circuit has been evaluated, all operations the prover performs are the (sum of) evaluation of polynomials in $R[\mathtt{X}]$ at random elements from A. Polynomial evaluation is (the sum of) the product of elements of R with elements of S. Hence, if the ratio between the product of two elements in R and the product of an element of R with an element of S is bigger than the constants hidden in the $O(|C|)$ complexity of the prover, this results in a *sublinear* time prover! We are only aware of two previous examples in the literature where the prover is sublinear in the size of the circuit: Matrix multiplication [Fre79, Tha13] and Fast Fourier Transforms (FFT) [LXZ21].

In [LXZ21], the authors provide a sum-check protocol for FFTs where the prover only needs to do additional $O(d)$ work to produce a proof for a vector of size d. This is sublinear, since the FFT complexity is $O(d \log d)$. If FFTs are used for fast polynomial multiplication, we also obtain sublinear time provers by taking R to be the polynomial ring and S its coefficient ring. Multiplying two degree-d polynomials requires either $O(d^2)$ or $O(d \log d)$ operations in S (since in practice, for smaller values of d the former approach might be preferable). Multiplying such a polynomial with an element of S, on the other hand, requires exactly d operations in S, which is a gap of either $O(d)$ or $O(\log d)$ between both approaches. Thus, with our protocol we obtain a sublinear prover for polynomial multiplication *regardless* of whether FFT is actually employed in practice.

For a matrix ring $R = \mathcal{M}_{n \times n}(S)$, we have that R is a free module of rank n^2 over S. Since the best matrix multiplication algorithms we know require way more than n^2 operations, we once again obtain a sublinear prover by applying the

observation at the beginning of this subsection. All in all, when taking every other complexity metric into account, Thaler's optimal MATMUL protocol [Tha13] is still preferable to our approach in terms of concrete efficiency. Nevertheless, we find interesting the extent to which our construction is versatile: We can obtain sublinear provers as simple, natural instantiations, rather than having to design a specific protocol. Furthermore, as far as we know, ours is only the third conceptually different method allowing for sublinear provers when dealing with matrix multiplication [Fre79, Tha13].

Even if they do not necessarily achieve sublinear time provers, many other rings R benefit from the improvement implied from being a rank-d module over a ring S. This is the case of many Clifford algebras, whose applications we discuss in the full version [Sor22]. For example, let $R = H(S)$ denote the quaternions with coefficients over a ring S. We have that $Z(R) = Z(S)$, and R is a free module of rank 4 over S. Multiplying two elements in R requires at least 7 multiplications in S for a commutative ring S (or at least 8 in the non-commutative case) [HL75]. Dual quaternions are of rank 8 over their coefficient ring S, whereas their product consists on three quaternion products. Hence, if S is commutative, the prover would roughly obtain a factor of $21/8 = 2.625$ improvement compared with running over [CCKP19] over S.

Theoretical improvements. If we furthermore assumed that addition and multiplication of elements of the chosen non-commutative ring R can be performed at unit cost, we can obtain a series of theoretical results. Even though one could imagine to have specific hardware for that goal, these observations remain mostly theoretical, as they require to work with exponential size rings.

First of all, in [HY11] Hrubeš and Yehudayoff show that given a polynomial f (over a ring S) of degree d in n variables, there is a non-commutative extension ring R such that $S \subset Z(R)$ and f has a a formula of size $O(dn)$ over R. On the other hand, if S is an algebraically closed field, no commutative extension ring R can reduce the formula or circuit complexity of f. These would all seem good news for us: Non-commutativity might be a requirement, the resulting formula is really small and furthermore R could potentially be a free module over S. Unfortunately, the dimension of this ring extension is roughly n^d.

In [SS10], Schott and Staples show how many **NP**-complete and ♯**P**-complete problems can be moved to class **P** if addition and multiplication in a Clifford algebra can be assumed to have unit cost. These include: Hamiltonian cycle problem, set covering problem, counting the edge-disjoint cycle decompositions of a finite graph, computing the permanent of an arbitrary matrix, computing the girth and circumference of a graph, and finding the longest path in a graph. Thus, in this model of computation, Theorem 3 provides us with a doubly-efficient IP for those languages[6]. Remember that, since for a language to have a doubly-efficient IP it has to belong to **BPP**, this was out of reach in the non-algebraic complexity world! Once again, the problem is that the algebra has an exponential dimension.

[6] In all precision, Theorem 3 only deals with layered arithmetic circuits, but our result can be generalized to general arithmetic circuits the same way as in [ZLW+21].

5 Doubly-efficient IP over non-commutative rings: Commutative, regular difference set

Our most general doubly-efficient IP supports rings that are possibly infinite and non-commutative, as long as they contain a commutative R.D. set A such that $A \subset R$. As a writing simplification, we will add the condition that[7] $\{0,1\} \subset A$. An example ring to which this section applies is $R = \mathcal{M}_{n\times n}(\mathbb{Z}/p^k\mathbb{Z})$ for a prime p. Since we can embed the Galois Ring $S = \mathsf{GR}(p^k, n)$ into R and S contains an exceptional set A of size p^n, we can pick that same A as our commutative, R.D. set [ES21]. On the other hand, we have that $Z(R) = \{a \cdot Id : a \in \mathbb{Z}/p^k\mathbb{Z}\}$, so the biggest regular difference set *contained* in $Z(R)$ is of size p. Hence, for small values of p, Section 4 might not be enough for soundness.

5.1 A new layer consistency equation

Let us look at Equation (1). The first problem when trying to generalize it to this setting, is that we cannot define MLEs of the $V_i : \{0,1\}^{s_i} \to R$ functions which map $b \in \{0,1\}^{s_i}$ to the b-th wire in the i-th layer. Instead, we need to content ourselves with either LMLEs or RMLEs for those functions (see Lemma 8). A natural impulse would be to settle for e.g. the LMLE $\hat{V}_L^{(i)}(\vec{\mathtt{Z}})$ and express the consistency with layer $i+1$ as follows, where $\widehat{\mathtt{add}}^{(i+1)}(\vec{\mathtt{Z}},\vec{\mathtt{X}},\vec{\mathtt{Y}}), \widehat{\mathtt{mult}}^{(i+1)}(\vec{\mathtt{Z}},\vec{\mathtt{X}},\vec{\mathtt{Y}}) \in R_A[\vec{\mathtt{X}},\vec{\mathtt{Y}},\vec{\mathtt{Z}}]_{\leq 1,0}$, $\hat{V}_L^{(i+1)}(\vec{\mathtt{X}}) \in R_A[\vec{\mathtt{X}}]_{\leq 1,0}$ and $\hat{V}_R^{(i+1)}(\vec{\mathtt{Y}}) \in R_A[\vec{\mathtt{Y}}]_{0,\leq 1}$:

$$\hat{V}_L^{(i)}(\vec{\mathtt{Z}}) = \sum_{x,y\in\{0,1\}^{s_{i+1}}} \Big(\widehat{\mathtt{mult}}^{(i+1)}(\vec{\mathtt{Z}},x,y)\cdot\big(\hat{V}_L^{(i+1)}(x)\cdot\hat{V}_R^{(i+1)}(y)\big) + \\ + \widehat{\mathtt{add}}^{(i+1)}(\vec{\mathtt{Z}},x,y)\cdot\big(\hat{V}_L^{(i+1)}(x)+\hat{V}_R^{(i+1)}(y)\big)\Big). \quad (3)$$

The right hand side is a *sandwich* polynomial in $R_A[\vec{\mathtt{X}},\vec{\mathtt{Y}},\vec{\mathtt{Z}}]_{\leq 1,\leq 1}$, since the coefficients of the wiring predicates belong to $Z(R)$. Having such a sandwich is problematic when defining a sum-check protocol, which would progress through univariate polynomials in each indeterminate by partially evaluating the right hand side of Eq. (3). More specifically, the problem is with the $\mathtt{Y}_j$ indeterminates (for $j = 1,\ldots,s_{i+1}$), as the partial evaluations sent by the prover would be *sandwich* polynomials $R_A[\mathtt{Y}_j]_{\leq 1,\leq 1}$. Since our Schwartz-Zippel lemma (Lemma 7) only copes with *toast* polynomials, this will not provide us with a sound protocol.

In order to have toast polynomials at every step of the sum-check protocol, we replace $\widehat{\mathtt{add}}^{(i+1)}(\vec{\mathtt{Z}},\vec{\mathtt{X}},\vec{\mathtt{Y}}), \widehat{\mathtt{mult}}^{(i+1)}(\vec{\mathtt{Z}},\vec{\mathtt{X}},\vec{\mathtt{Y}}) \in R_A[\vec{\mathtt{Z}},\vec{\mathtt{X}},\vec{\mathtt{Y}}]_{\leq 1,0}$ in Eq.(3) with $\widehat{\mathtt{add}}_{\mathtt{L}}^{(i+1)}(\vec{\mathtt{Z}},\vec{\mathtt{X}},\vec{\mathtt{W}}), \widehat{\mathtt{mult}}_{\mathtt{L}}^{(i+1)}(\vec{\mathtt{Z}},\vec{\mathtt{X}},\vec{\mathtt{W}}) \in R_A[\vec{\mathtt{Z}},\vec{\mathtt{X}},\vec{\mathtt{W}}]_{\leq 1,0}$, still evaluating $\vec{\mathtt{W}}$ in y. This seemingly minor change requires to develop a new sum-check protocol which

[7] We can remove that simplification and work with polynomials in $R_{A\cup\{0,1\}}[\vec{\mathtt{U}},\vec{\mathtt{W}},\vec{\mathtt{X}},\vec{\mathtt{Y}}]_{\leq 2,\leq 2}$ rather than $R_A[\vec{\mathtt{U}},\vec{\mathtt{W}},\vec{\mathtt{X}},\vec{\mathtt{Y}}]_{\leq 2,\leq 2}$, since if A is a commutative set, so is $A\cup\{0,1\}$. For the purpose of clarity, we avoid that notation.

ensures that $\mathcal{P}$ evaluates $\vec{\mathtt{Y}}$ and $\vec{\mathtt{W}}$ at the same y. For the layer consistency equations featuring $\hat{V}_R^{(i)}(\vec{\mathtt{Z}}) \in R_A[\vec{\mathtt{Z}}]_{0,\leq 1}$, we will also do a change of variables, as we describe in Lemma 9 in Appendix **??**. We display that information in Table 1.

Polynomial	$\widehat{\mathtt{add}_{\mathtt{L}}}^{(i+1)}, \widehat{\mathtt{mult}_{\mathtt{L}}}^{(i+1)}$	$\widehat{\mathtt{add}_{\mathtt{R}}}^{(i+1)}, \widehat{\mathtt{mult}_{\mathtt{R}}}^{(i+1)}$	$\hat{V}_L^{(i+1)}$	$\hat{V}_R^{(i+1)}$	$\hat{V}_L^{(i)}$	$\hat{V}_R^{(i)}$
(L/R)MLE	MLE	MLE	LMLE	RMLE	LMLE	RMLE
Ring	$R_A[\vec{\mathtt{X}}, \vec{\mathtt{W}}, \vec{\mathtt{Z}}]_{\leq 1,0}$	$R_A[\vec{\mathtt{Y}}, \vec{\mathtt{U}}, \vec{\mathtt{Z}}]_{\leq 1,0}$	$R_A[\vec{\mathtt{X}}]_{\leq 1,0}$	$R_A[\vec{\mathtt{Y}}]_{0,\leq 1}$	$R_A[\vec{\mathtt{Z}}]_{\leq 1,0}$	$R_A[\vec{\mathtt{Z}}]_{0,\leq 1}$

Table 1. Polynomials involved in layer consistency equations. Note that MLEs such as $\widehat{\mathtt{add}_{\mathtt{L}}}^{(i+1)}$ could be considered as either polynomials in $R_A[\vec{\mathtt{X}}, \vec{\mathtt{W}}, \vec{\mathtt{Z}}]_{\leq 1,0}$ or $R_A[\vec{\mathtt{X}}, \vec{\mathtt{W}}, \vec{\mathtt{Z}}]_{0,\leq 1}$.

Lemma 9. *Let $\vec{\mathtt{Z}} = (\mathtt{Z}_1, \ldots, \mathtt{Z}_{s_i})$. Toast multilinear polynomials $\hat{V}_L^{(i)} \in R_A[\vec{\mathtt{Z}}]_{\leq 1,0}$ and $\hat{V}_R^{(i)} \in R_A[\vec{\mathtt{Z}}]_{0,\leq 1}$ are equal to the following expressions:*

$$\hat{V}_L^{(i)}(\vec{\mathtt{Z}}) = \sum_{x,y \in \{0,1\}^{s_{i+1}}} \Big(\widehat{\mathtt{mult}_L}^{(i+1)}(\vec{\mathtt{Z}}, x, y) \cdot \big(\hat{V}_L^{(i+1)}(x) \cdot \hat{V}_R^{(i+1)}(y) \big) + \\ + \ \widehat{\mathtt{add}_L}^{(i+1)}(\vec{\mathtt{Z}}, x, y) \cdot \big(\hat{V}_L^{(i+1)}(x) + \hat{V}_R^{(i+1)}(y) \big) \Big). \quad (4)$$

$$\hat{V}_R^{(i)}(\vec{\mathtt{Z}}) = \sum_{x,y \in \{0,1\}^{s_{i+1}}} \Big(\big(\hat{V}_L^{(i+1)}(x) \cdot \hat{V}_R^{(i+1)}(y) \big) \cdot \widehat{\mathtt{mult}_R}^{(i+1)}(\vec{\mathtt{Z}}, x, y) + \\ + \ \big(\hat{V}_L^{(i+1)}(x) + \hat{V}_R^{(i+1)}(y) \big) \cdot \widehat{\mathtt{add}_R}^{(i+1)}(\vec{\mathtt{Z}}, x, y) \Big). \quad (5)$$

Where, in Eq. (4), $\widehat{\mathtt{add}_L}^{(i+1)}(\vec{\mathtt{Z}}, \vec{\mathtt{X}}, \vec{\mathtt{W}}), \widehat{\mathtt{mult}_L}^{(i+1)}(\vec{\mathtt{Z}}, \vec{\mathtt{X}}, \vec{\mathtt{W}}) \in R_A[\vec{\mathtt{X}}, \vec{\mathtt{W}}, \vec{\mathtt{Z}}]_{\leq 1,0}$ and in Eq. (5), $\widehat{\mathtt{add}_R}^{(i+1)}(\vec{\mathtt{Z}}, \vec{\mathtt{U}}, \vec{\mathtt{Y}}), \widehat{\mathtt{mult}_R}^{(i+1)}(\vec{\mathtt{Z}}, \vec{\mathtt{U}}, \vec{\mathtt{Y}}) \in R_A[\vec{\mathtt{Y}}, \vec{\mathtt{U}}, \vec{\mathtt{Z}}]_{\leq 1,0}$.

Proof. The term on each side of Eq. (4) (resp. Eq. (5)) is a multilinear polynomial in $R_A[\vec{\mathtt{Z}}]_{\leq 1,0}$ (resp. $R_A[\vec{\mathtt{Z}}]_{0,\leq 1}$), so by the uniqueness of LMLEs (resp. RMLEs), we are done if their evaluation at every $z \in \{0,1\}^{s_i}$ coincides. The latter follows from the definitions of $\widehat{\mathtt{add}_{\mathtt{L}}}^{(i+1)}, \widehat{\mathtt{mult}_{\mathtt{L}}}^{(i+1)}$ (resp. $\widehat{\mathtt{add}_{\mathtt{R}}}^{(i+1)}, \widehat{\mathtt{mult}_{\mathtt{R}}}^{(i+1)}$). ∎

Remark 1. An interesting detail about this construction, in which $A \not\subset Z(R)$, is that it is necessary for wiring predicates to be MLEs, rather than simply LMLEs or RMLEs. Otherwise, we would not obtain toast polynomials (in the $\mathtt{X}_i$ variables for Equation (4), in $\mathtt{Y}_i$ variables for Equation (5)) throughout the execution of the sumcheck protocol and we would be unable to apply Lemma 7 to determine soundness. Whereas for the standard addition and multiplication gates (since $\{0,1\} \subseteq Z(R) \subseteq C_R(A)$) we always obtain MLEs, if we use more complex wiring predicates which enable multiplication by hard-coded constants, those constants have to belong to $C_R(A)$.

5.2 2-to-1 reduction

Our protocol starts with a simple layer consistency equation, which relates the output layer with layer 1 in the circuit according to the following equation:

$$\hat{V}_L^{(0)}(\gamma) = \sum_{x,y\in\{0,1\}^{s_1}} \Big(\widehat{\texttt{mult}}_{\texttt{L}}^{(1)}(\gamma,x,y)\cdot\big(\hat{V}_L^{(1)}(x)\cdot\hat{V}_R^{(1)}(y)\big)+ \\ +\widehat{\texttt{add}}_{\texttt{L}}^{(1)}(\gamma,x,y)\cdot\big(\hat{V}_L^{(1)}(x)+\hat{V}_R^{(1)}(y)\big)\Big). \tag{6}$$

At the conclusion of the sumcheck protocol which is run to verify Equation (6), $\mathcal{V}$ needs to evaluate $\widehat{\texttt{mult}}_{\texttt{L}}^{(1)}(\gamma,\vec{\texttt{X}},\vec{\texttt{W}})\cdot(\hat{V}_L^{(1)}(\vec{\texttt{X}})\cdot\hat{V}_R^{(1)}(\vec{\texttt{Y}}))+\widehat{\texttt{add}}_{\texttt{L}}^{(1)}(\gamma,\vec{\texttt{X}},\vec{\texttt{W}})\cdot(\hat{V}_L^{(1)}(\vec{\texttt{X}})+\hat{V}_R^{(1)}(\vec{\texttt{Y}}))$ by replacing $\vec{\texttt{X}},\vec{\texttt{Y}},\vec{\texttt{W}}$ with respective random values $\chi^{(0)},\psi^{(0)},\omega^{(0)}\in A^{s_1}$. Since $\mathcal{V}$ cannot compute neither $\hat{V}_L^{(1)}(\chi^{(0)})$ nor $\hat{V}_R^{(1)}(\psi^{(0)})$ on their own, $\mathcal{P}$ will provide those values. These alleged evaluations have to satisfy their corresponding layer consistency equations, using LMLEs and RMLEs respectively. In order to avoid an exponential blow-up in the depth of the circuit, we perform a reduction from the two claimed values $\hat{V}_L^{(1)}(\chi^{(0)}),\hat{V}_R^{(1)}(\psi^{(0)})$ to a single one. We do so by sampling random values $\alpha^{(1)},\beta^{(1)}\in A$ and combining their corresponding layer consistency equations as it is described next:

$$\alpha^{(i)}\hat{V}_L^{(i)}(\chi^{(i-1)})+\beta^{(i)}\hat{V}_R^{(i)}(\psi^{(i-1)}) = \sum_{x,y\in\{0,1\}^{s_{i+1}}} \\ \Big(\quad \alpha^{(i)}\cdot\widehat{\texttt{mult}}_{\texttt{L}}^{(i+1)}(\chi^{(i-1)},x,y)\cdot(\hat{V}_L^{(i+1)}(x)\cdot\hat{V}_R^{(i+1)}(y))+ \\ +\beta^{(i)}\cdot(\hat{V}_L^{(i+1)}(x)\cdot\hat{V}_R^{(i+1)}(y))\cdot\widehat{\texttt{mult}}_{\texttt{R}}^{(i+1)}(\psi^{(i-1)},x,y)+ \\ +\alpha^{(i)}\cdot\widehat{\texttt{add}}_{\texttt{L}}^{(i+1)}(\chi^{(i-1)},x,y)\cdot(\hat{V}_L^{(i+1)}(x)+\hat{V}_R^{(i+1)}(y))+ \\ +\beta^{(i)}\cdot(\hat{V}_L^{(i+1)}(x)+\hat{V}_R^{(i+1)}(y))\cdot\widehat{\texttt{add}}_{\texttt{R}}^{(i+1)}(\psi^{(i-1)},x,y)\quad\Big) \tag{7}$$

A justification for the soundness of the previous equation, as well as the two original layer consistency equations appears in the full version [Sor22], where we also provide a different approach using a 4-to-2 reduction, which reduces round complexity at the cost of increased communication.

5.3 Sum-check for non-commutative layer consistency

We provide the sum-check protocol for Equation (7)[8]. The specific algorithm run by the prover and its complexity analysis appears in Appendix A. Remember that $A\supseteq H=\{0,1\}$ is an R.D. commutative set.

[8] The simpler protocol for Equation (6) can be found in the full version.

Sum-check protocol for Equation (7): Let $\vec{x} = (x_1, \ldots, x_m)$, $\vec{y} = (y_1, \ldots, y_m)$. We provide a sum-check protocol for $\sum_{\vec{x},\vec{y} \in H^m} f(\vec{x}, \vec{y}, \vec{x}, \vec{y}) = \beta$, where $f \in R_A[\vec{\mathtt{U}}, \vec{\mathtt{W}}, \vec{\mathtt{X}}, \vec{\mathtt{Y}}]_{\leq 2, \leq 2}$. If any of the checks throughout the protocol fails, $\mathcal{V}$ rejects.

1. In the first round, for $b \in \{0, 1\}$, $\mathcal{P}$ computes $g_{1,b} \in R_A[\mathtt{U}_1]_{0,\leq 1}$, given by:

$$g_{1,b}(\mathtt{U}_1) = \sum_{\substack{x_2, \ldots, x_m \in H \\ \vec{y} \in H^m}} f(\mathtt{U}_1, x_2, \ldots, x_m, \vec{y}, b, x_2, \ldots, x_m, \vec{y}),$$

   and sends them to $\mathcal{V}$. Then $\mathcal{V}$ checks whether $g_{1,0}, g_{1,1} \in R_A[\mathtt{U}_1]_{0,\leq 1}$ and $\sum_{b \in H} g_{1,b}(b) = \beta$. If true, $\mathcal{V}$ chooses a random $r_1 \in A$ and sends it to $\mathcal{P}$.
2. For rounds $2 \leq i \leq m$, define $\vec{x}_{(i,m]} = (x_{i+1}, \ldots, x_m)$ and $\vec{x}_{[1,i)} = (x_1, \ldots, x_{i-1})$. $\mathcal{P}$ sends the univariate toast polynomials $g_{i,0}, g_{i,1} \in R_A[\mathtt{U}_i]_{0,\leq 1}$ given by:

$$g_{i,b}(\mathtt{U}_i) = \sum_{\substack{\vec{x}_{[1,i)} \in H^{i-1}, \vec{x}_{(i,m]} \in H^{m-i} \\ \vec{y} \in H^m}} f(r_1, \ldots, r_{i-1}, \mathtt{U}_i, \vec{x}_{(i,m]}, \vec{y}, \vec{x}_{[1,i)}, b, \vec{x}_{(i,m]}, \vec{y}),$$

   $\mathcal{V}$ checks whether $g_{i,b} \in R_A[\mathtt{U}_i]_{0,\leq 1}$ and $\sum_{b \in H} g_{i,b}(b) - g_{i-1,b}(r_{i-1}) = 0$. If that is the case, $\mathcal{V}$ chooses a random element $r_i \in A$ and sends it to $\mathcal{P}$.
3. For rounds $m + 1 \leq i \leq 2m$, $\mathcal{P}$, define $j = i - m$, $\vec{r}_{[1,i)} = (r_1, \ldots, r_{i-1})$, $\vec{y}_{(j,m]} = (y_{j+1}, \ldots, y_m)$ and $\vec{y}_{[1,j)} = (y_1, \ldots, y_{j-1})$. $\mathcal{P}$ sends the univariate toast polynomials $g_{i,0}, g_{i,1} \in R_A[\mathtt{W}_j]_{\leq 1,0}$ given by:

$$g_{i,b}(\mathtt{W}_j) = \sum_{\substack{\vec{y}_{[1,j)} \in H^{j-1}, \vec{y}_{(j,m]} \in H^{m-j} \\ \vec{x} \in H^m}} f(\vec{r}_{[1,i)}, \mathtt{W}_j, \vec{y}_{(j,m]}, \vec{x}, \vec{y}_{[1,j)}, b, \vec{y}_{(j,m]}),$$

   $\mathcal{V}$ checks whether $g_{i,0}, g_{i,1} \in R_A[\mathtt{W}_j]_{\leq 1,0}$ and $\sum_{b \in H} g_{i,b}(b) - g_{i-1,b}(r_{i-1}) = 0$. If that is the case, $\mathcal{V}$ chooses a random element $r_i \in A$ and sends it to $\mathcal{P}$.
4. For round $i = 2m+1$, define $\vec{r}_{[1,2m+1)} = (r_1, \ldots, r_{2m})$ and $\vec{x}_{(1,m]} = (x_2, \ldots, x_m)$. $\mathcal{P}$ sends the toast polynomial $g_{2m+1} \in R_A[\mathtt{X}_1]_{\leq 2,0}$:

$$g_{2m+1}(\mathtt{X}_1) = \sum_{\vec{x}_{(1,m]} \in H^{m-1}, \vec{y} \in H^m} f(\vec{r}_{[1,2m+1)}, \mathtt{X}_1, \vec{x}_{(1,m]}, \vec{y}),$$

   $\mathcal{V}$ checks whether $g_{2m+1} \in R_A[\mathtt{X}_1]_{\leq 2,0}$ and $\sum_{b \in H} g_{2m+1}(b) - g_{2m,b}(r_{2m}) = 0$. If so, $\mathcal{V}$ chooses a random element $r_{2m+1} \in A$ and sends it to $\mathcal{P}$.
5. For rounds $2m + 2 \leq i \leq 3m$, define $j = i - 2m$, $\vec{r}_{[1,i)} = (r_1, \ldots, r_{i-1})$ and $\vec{x}_{(j,m]} = (x_{j+1}, \ldots, x_m)$. $\mathcal{P}$ sends the toast polynomial $g_i \in R_A[\mathtt{X}_j]_{\leq 2,0}$:

$$g_i(\mathtt{X}_j) = \sum_{\vec{x}_{(j,m]} \in H^{m-j}, \vec{y} \in H^m} f(\vec{r}_{[1,i)}, \mathtt{X}_j, \vec{x}_{(j,m]}, \vec{y})$$

   $\mathcal{V}$ checks whether $g_i \in R_A[\mathtt{X}_j]_{\leq 2,0}$ and $\sum_{b \in H} g_i(b) = g_{i-1}(r_{i-1})$. If that is the case, $\mathcal{V}$ chooses a random element $r_i \in A$ and sends it to $\mathcal{P}$.

6. For rounds $3m+1 \le i \le 4m$, define $j = i - 3m$, $\vec{r}_{[1,i)} = (r_1, \ldots, r_{i-1})$ and $\vec{y}_{(j,m]} = (y_{j+1}, \ldots, y_m)$. $\mathcal{P}$ sends the toast polynomial $g_i \in R_A[\mathtt{Y}_j]_{0,\le 2}$:

$$g_i(\mathtt{Y}_j) = \sum_{\vec{y}_{(j,m]} \in H^{m-j}} f(\vec{r}_{[1,i)}, \mathtt{Y}_j, \vec{y}_{(j,m]}),$$

   $\mathcal{V}$ checks whether $g_i \in R_A[\mathtt{Y}_j]_{0,\le 2}$ and $\sum_{b \in H} g_i(b) = g_{i-1}(r_{i-1})$. If that is the case, $\mathcal{V}$ chooses a random element $r_i \in A$ and sends it to $\mathcal{P}$.
7. After the $4m$-th round, $\mathcal{V}$ checks whether $g_{4m}(r_{4m}) = f(r_1, \ldots, r_{4m})$ by querying[9] its oracles at $(r_1, \ldots, r_{4m})$.

Theorem 4. *Let A be a commutative R.D. set such that $\{0,1\} \subseteq A$. Let $f \in R_A[\vec{\mathtt{U}}, \vec{\mathtt{W}}, \vec{\mathtt{X}}, \vec{\mathtt{Y}}]_{\le 2, \le 2}$ be the multi-variate sandwich polynomial given by Equation (7). The sum-check protocol is a public coin interactive proof with soundness error $\le 8m \cdot |A|^{-1}$. The communication complexity is $14m$ elements in R.*

5.4 Putting everything together

Doubly-efficient interactive proof over a non-commutative ring

Input: Circuit input `inp` and claimed output `out`. **Output:** Accept or reject.

- Compute $\hat{V}_L^{(0)}(\mathtt{X})$ as the LMLE of `out`. $\mathcal{V}$ chooses a random $\gamma \in A^{s_0}$ and sends it to $\mathcal{P}$. Both parties compute $\hat{V}_L^{(0)}(\gamma)$.
- Run a sum-check protocol on Equation (6) as described in the full version. Let $\chi^{(0)}, \psi^{(0)}, \omega^{(0)}$ denote the challenge vectors corresponding to the $\vec{\mathtt{X}}$, $\vec{\mathtt{Y}}$ and $\vec{\mathtt{W}}$ variables within that execution. $\mathcal{P}$ sends $\hat{V}_L^{(1)}(\chi^{(0)})$ and $\hat{V}_R^{(1)}(\psi^{(0)})$ to $\mathcal{V}$.
- $\mathcal{V}$ queries their oracles for $\widehat{\mathtt{mult}}_{\mathtt{L}}^{(1)}(\gamma, \chi^{(0)}, \omega^{(0)})$ and $\widehat{\mathtt{add}}_{\mathtt{L}}^{(1)}(\gamma, \chi^{(0)}, \omega^{(0)})$, so as to check that $\widehat{\mathtt{add}}_{\mathtt{L}}^{(1)}(\gamma, \chi^{(0)}, \omega^{(0)}) \cdot (\hat{V}_L^{(1)}(\chi^{(0)}) + \hat{V}_R^{(1)}(\psi^{(0)})) + \widehat{\mathtt{mult}}_{\mathtt{L}}^{(1)}(\gamma, \chi^{(0)}, \omega^{(0)}) \cdot (\hat{V}_L^{(1)}(\chi^{(0)}) \cdot \hat{V}_R^{(1)}(\psi^{(0)}))$ equals the last message of the sumcheck execution.
- For circuit layers $i = 1, \ldots, D-1$, $\mathcal{V}$ samples $\alpha^{(i)}, \beta^{(i)} \in A$ and sends them to $\mathcal{P}$. They run a sumcheck protocol on Equation (7) as described in Figure 2 in Appendix A. Let $\chi^{(i)}, \psi^{(i)}$ denote the challenge vectors corresponding to the $\vec{\mathtt{X}}$, and $\vec{\mathtt{Y}}$ variables within that execution. At the end of the protocol, $\mathcal{P}$ sends $\hat{V}_L^{(i+1)}(\chi^{(i)})$ and $\hat{V}_R^{(i+1)}(\psi^{(i)})$ to $\mathcal{V}$, so that $\mathcal{V}$ can check the validity of the last message in the sumcheck execution. If the check passes, they proceed to the $(i+1)$-th layer, otherwise, $\mathcal{V}$ outputs reject and aborts.
- At the input layer D, $\mathcal{V}$ has received two claims $\hat{V}_L^{(D)}(\chi^{(D-1)})$ and $\hat{V}_R^{(D)}(\psi^{(D-1)})$. $\mathcal{V}$ queries the evaluation oracles of $\hat{V}_L^{(D)}$ and $\hat{V}_R^{(D)}$ at $\chi^{(D-1)}$ and $\psi^{(D-1)}$ respectively, and checks that they equal the sumcheck claims. If they do, $\mathcal{V}$ outputs accept, otherwise, $\mathcal{V}$ outputs reject.

Fig. 1. Doubly-efficient IP over a ring containing a commutative, regular difference set.

[9] As usual in the GKR protocol, some values are actually provided by $\mathcal{P}$, unless the input layer has been reached. This step is more detailed in Figure 1.

Theorem 5. *Let R be a ring and $A \subset R$ a commutative, regular difference set such that $\{0,1\} \subset A$ Let $C : R^n \to R^k$ be a depth-D layered arithmetic circuit. Figure 1 is an interactive proof for C with soundness error $O(D \log |C|/|A|)$. Its round complexity is $O(D \log |C|)$ and it communicates $O(D \log |C|)$ elements in R. In terms of operations in R, the prover complexity is $O(|C|)$ and the verifier complexity is $O(n + k + D \log |C| + T)$, where T is the optimal time to evaluate every wiring predicate ($\widehat{\texttt{add}}_L^{(i)}, \widehat{\texttt{mult}}_L^{(i)}, \widehat{\texttt{add}}_R^{(i)}, \widehat{\texttt{mult}}_R^{(i)}$). For log-space uniform circuits, $T = \mathsf{poly}\log(|C|)$ and hence the IP is succinct.*

A Linear time Prover for Equation (7)

Multi-linear extensions were key for [CMT12] to improve the complexity of the Prover in [GKR15] from $\mathsf{poly}(|C|)$ to $O(|C|\log(|C|))$. In this section, we will show how to improve upon this to a complexity of $O(|C|)$, in a style similar to Libra [XZZ+19]. In order to achieve this, we will show how the Prover can execute the sum-check algorithm of Section 5.3 for Equation (7). Recall that $\mathcal{P}$ has to sum the evaluations of $f \in R_A[\vec{\mathtt{U}}, \vec{\mathtt{W}}, \vec{\mathtt{X}}, \vec{\mathtt{Y}}]_{\leq 2,\leq 2}$ in the hypercube H^{4m}, where $H = \{0, 1\}$. Our following algorithms assume that $\mathcal{P}$ has an initial lookup table (LUT) $\boldsymbol{T}_f$ with these evaluations, as well as the same kind of lookup tables for its constituent (L/R)MLEs $\boldsymbol{T}_{\widehat{\mathtt{mult}_{\mathtt{L}}}}$,$\boldsymbol{T}_{\widehat{\mathtt{add}_{\mathtt{L}}}}$,$\boldsymbol{T}_{\hat{V}_L}$,$\boldsymbol{T}_{\widehat{\mathtt{mult}_{\mathtt{R}}}}$,$\boldsymbol{T}_{\widehat{\mathtt{add}_{\mathtt{R}}}}$,$\boldsymbol{T}_{\hat{V}_R}$. We also assume that $\mathcal{P}$ has received and stored the 2-to-1 reduction challenges $\alpha, \beta \in A$. For a simpler write-up, we write the different algorithms as if $\mathcal{P}$ already knew the challenge vector $\vec{r} = (r_1, \ldots, r_{4m}) \in A^{4m}$, even though they will receive the different r_i values as the progress through the execution of the sum-check protocol.

In constrast with [XZZ+19], we make the Prover provide the Verifier with explicit polynomials, rather than with their evaluations at (up to) three different points. We do this for the sake of generality[10], since interpolation requires exceptional rather than regular-difference sets, and the target ring (e.g. $\mathbb{Z}$) might not contain a commutative exceptional set of size three.

$\vec{\mathtt{U}}, \vec{\mathtt{W}}$ variables (Step 1). This is the easiest phase, since we can directly reason about $f \in R_A[\vec{\mathtt{U}}, \vec{\mathtt{W}}, \vec{\mathtt{X}}, \vec{\mathtt{Y}}]_{\leq 2,\leq 2}$ from Equation (7) and its LUT $\boldsymbol{T}_f$. `Sumcheck_`$\{\mathtt{U}, \mathtt{W}\}$ (Figure 4) provides with the polynomials for these first $2m$ messages. All terms in the sums of Figure 4 can be found, in turn, in the lookup table $\mathcal{F}$ produced by `Function_Evaluations_`$\{\mathtt{U}, \mathtt{W}\}$ (Figure 3).

The algorithm in Figure 3 follows from the simple observation that, because of linearity, any RMLE $f(\vec{r}, \mathtt{U}_i, \vec{t}) \in R_A[\mathtt{U}_i]_{0,\leq 1}$ satisfies that $f(\vec{r}, \mathtt{U}_i, \vec{t}) = (f(\vec{r}, 1, \vec{t}) -$

[10] It would be easy to modify our algorithms to work by providing polynomial evaluations instead. In fact, the set $\{0, 1, \gamma\}$ is commutative and exceptional as long as γ and $\gamma - 1$ are invertible. If 2 is not a zero divisor, we can always pick $\gamma = 2$. Otherwise we may still find such γ easily (as e.g. in $\mathbb{F}_{2^d}, \mathsf{GR}(2^k, d), \mathcal{M}_{n\times n}(\mathbb{Z}/2^k\mathbb{Z})$) or resort to ring extensions (e.g. embed $\mathbb{Z}/2^k\mathbb{Z}$ in $\mathsf{GR}(2^k, d)$ or $\mathbb{Z}$ in $\mathbb{R}$).

Algorithm

$\texttt{Linear\_}\mathcal{P}\texttt{\_Consistency}(\boldsymbol{T}_f, \boldsymbol{T}_{\widehat{\texttt{mult}_\texttt{L}}}, \boldsymbol{T}_{\widehat{\texttt{add}_\texttt{L}}}, \boldsymbol{T}_{\hat{V}_L}, \boldsymbol{T}_{\widehat{\texttt{mult}_\texttt{R}}}, \boldsymbol{T}_{\widehat{\texttt{add}_\texttt{R}}}, \boldsymbol{T}_{\hat{V}_R}, \vec{\chi}, \vec{\psi}, \alpha, \beta, \vec{r})$

Input: $f \in R_A[\vec{\texttt{U}}, \vec{\texttt{W}}, \vec{\texttt{X}}, \vec{\texttt{Y}}]_{\leq 2, \leq 2}$ from Equation (7) and its initial lookup table $\boldsymbol{T}_f$. Initial lookup tables of its constituent polynomials $\boldsymbol{T}_{\widehat{\texttt{mult}_\texttt{L}}}, \boldsymbol{T}_{\widehat{\texttt{add}_\texttt{L}}}, \boldsymbol{T}_{\hat{V}_L}, \boldsymbol{T}_{\widehat{\texttt{mult}_\texttt{R}}}, \boldsymbol{T}_{\widehat{\texttt{add}_\texttt{R}}}, \boldsymbol{T}_{\hat{V}_R}$. Challenge vector $\vec{r} = (r_1, \ldots, r_{4m}) \in A^{4m}$ and 2-to-1 reduction challenges $\alpha, \beta \in A$.
Output: Sum-check messages for the layer consistency Equation (7).

1. Run $\texttt{Sumcheck\_}\{\texttt{U}, \texttt{W}\}(f, \boldsymbol{T}_f, \vec{r}_{[1,2m]})$ as described in Figure 4.
2. Run $\texttt{Setup\_X}(\widehat{\texttt{mult}_\texttt{L}}, \boldsymbol{T}_{\widehat{\texttt{mult}_\texttt{L}}}, \widehat{\texttt{add}_\texttt{L}}, \boldsymbol{T}_{\widehat{\texttt{add}_\texttt{L}}}, \widehat{\texttt{mult}_\texttt{R}}, \boldsymbol{T}_{\widehat{\texttt{mult}_\texttt{R}}}, \widehat{\texttt{add}_\texttt{R}}, \boldsymbol{T}_{\widehat{\texttt{add}_\texttt{R}}}, \vec{\chi}, \vec{\psi}, \vec{r}_{[1,2m]})$ as described in Figure 7 in order to obtain $\{\boldsymbol{T}_{\widehat{\texttt{mult}_\texttt{L}}}(x), \boldsymbol{T}_{\widehat{\texttt{add}_\texttt{L}}}(x), \boldsymbol{T}_{\widehat{\texttt{mult}_\texttt{R}}}(y), \boldsymbol{T}_{\widehat{\texttt{add}_\texttt{R}}}(y)\}$.
3. $\mathcal{F}_{\hat{V}_L} \leftarrow \texttt{Function\_Evaluations}(\hat{V}_L, \boldsymbol{T}_{\hat{V}_L}, r_{2m+1}, \ldots, r_{3m})$.
4. Run $\texttt{Sumcheck\_X\_Left}(\widehat{\texttt{mult}_\texttt{L}}, \boldsymbol{T}_{\widehat{\texttt{mult}_\texttt{L}}}, \widehat{\texttt{add}_\texttt{L}}, \boldsymbol{T}_{\widehat{\texttt{add}_\texttt{L}}}, \mathcal{F}_{\hat{V}_L}, \hat{V}_R, \boldsymbol{T}_{\hat{V}_R}, \vec{r}_{[2m+1,3m]})$ as described in Figure 8 in order to obtain $\{g_{2m+i}^{\texttt{mult}_\texttt{L}}(\texttt{X}_i), g_{2m+i}^{\texttt{add}_\texttt{L}}(\texttt{X}_i)\}_{i=1}^m$.
5. Run $\texttt{Sumcheck\_X\_Right}(\widehat{\texttt{mult}_\texttt{R}}, \boldsymbol{T}_{\widehat{\texttt{mult}_\texttt{R}}}, \widehat{\texttt{add}_\texttt{R}}, \boldsymbol{T}_{\widehat{\texttt{add}_\texttt{R}}}, \mathcal{F}_{\hat{V}_L}, \hat{V}_R, \boldsymbol{T}_{\hat{V}_R}, \vec{r}_{[2m+1,3m]})$ as described in Figure 9 in order to obtain $\{g_{2m+i}^{\texttt{mult}_\texttt{R}}(\texttt{X}_i), g_{2m+i}^{\texttt{add}_\texttt{R}}(\texttt{X}_i)\}_{i=1}^m$.
6. For $i \in [m]$, compute:

$$g_{2m+i}(\texttt{X}_i) = \alpha \cdot \left(g_{2m+i}^{\texttt{mult}_\texttt{L}}(\texttt{X}_i) + g_{2m+i}^{\texttt{add}_\texttt{L}}(\texttt{X}_i)\right) + \beta \cdot \left(g_{2m+i}^{\texttt{mult}_\texttt{R}}(\texttt{X}_i) + g_{2m+i}^{\texttt{add}_\texttt{R}}(\texttt{X}_i)\right).$$

7. Run $\texttt{Setup\_Y}(\widehat{\texttt{mult}_\texttt{L}}, \boldsymbol{T}_{\widehat{\texttt{mult}_\texttt{L}}}, \widehat{\texttt{add}_\texttt{L}}, \boldsymbol{T}_{\widehat{\texttt{add}_\texttt{L}}}, \vec{r}_{[2m+1,3m]})$ as described in Figure 10.
8. In order to obtain $\{g_{3m+i}(\texttt{Y}_i)\}_{i=1}^m$, run $\texttt{Sumcheck\_Y}(\widehat{\texttt{mult}_\texttt{R}}, \boldsymbol{T}_{\widehat{\texttt{mult}_\texttt{R}}}, \widehat{\texttt{add}_\texttt{R}}, \boldsymbol{T}_{\widehat{\texttt{add}_\texttt{R}}}, \hat{V}_R, \boldsymbol{T}_{\hat{V}_R}, \hat{V}_L(\vec{r}_{[2m+1,3m]}), \alpha \cdot \widehat{\texttt{mult}_\texttt{L}}(\vec{\chi}, \vec{r}_{[m+1,3m]}), \alpha \cdot \widehat{\texttt{add}_\texttt{L}}(\vec{\chi}, \vec{r}_{[m+1,3m]}), \vec{r}_{[3m+1,4m]}, \beta)$ as described in Figure 11.

Fig. 2. Linear time prover for the sum-check protocol in Section 5.3.

$f(\vec{r},0,\vec{t})\cdot \mathtt{U}_i + f(\vec{r},0,\vec{t})$. Notice that, whereas the initial lookup table $\boldsymbol{T}_f$ contains all the 2^{4m} evaluations of f from Equation (7) in $H=\{0,1\}$, modifications only occur on the first $2m$ indices, which are the ones related to variables $\mathtt{U}$ and $\mathtt{W}$.

Algorithm $\mathtt{Function\_Evaluations\_\{U,W\}}(f, \boldsymbol{T}_f, r_1, \ldots, r_{2m})$

Input: $f \in R_A[\vec{\mathtt{U}},\vec{\mathtt{W}},\vec{\mathtt{X}},\vec{\mathtt{Y}}]_{\leq 2,\leq 2}$ from Equation (7), initial lookup table $\boldsymbol{T}_f$, random challenges $\vec{r}=(r_1,\ldots,r_{2m}) \in A^{2m}$.
Output: Polynomials $f(r_1,\ldots,r_{i-1},\mathtt{U}_i,\vec{t}_{i,b}) \in R_A[\mathtt{U}_i]_{0,\leq 1}$ for $i \in [1,m]$ and $\vec{t}_{i,b} \in H^{4m-i}$. Polynomials $f(r_1,\ldots,r_{i-1},\mathtt{W}_{i-m},\vec{t}_{i,b}) \in R_A[\mathtt{W}_{i-m}]_{\leq 1,0}$ for $i \in [m+1,2m]$ and $\vec{t}_{i,b} \in H^{4m-i}$.

- For $i \in [1,2m]$ let $\vec{0}$ be the length-$(i-1)$ zero vector and $r_{[1,i)} = (r_1,\ldots,r_{i-1})$.
  - For $i \in [1,m]$: For $b \in H$, and for every $\vec{y} \in H^m$, $\vec{x}_{(i,m]} \in H^{m-i}$, $\vec{x}_{[1,i)} \in H^{i-1}$, define $\vec{t}_{i,b} = (\vec{x}_{(i,m]},\vec{y},\vec{x}_{[1,i)},b,\vec{x}_{(i,m]},\vec{y}) \in H^{4m-i}$ and do:

$$\begin{aligned} f(r_{[1,i)},\mathtt{U}_i,\vec{t}_{i,b}) &\leftarrow \boldsymbol{T}_f[\vec{0},1,\vec{t}_{i,b}]\cdot \mathtt{U}_i + \boldsymbol{T}_f[\vec{0},0,\vec{t}_{i,b}]\cdot(1-\mathtt{U}_i) \\ \boldsymbol{T}_f[\vec{0},0,\vec{t}_{i,b}] &\leftarrow \boldsymbol{T}_f[\vec{0},1,\vec{t}_{i,b}]\cdot r_i + \boldsymbol{T}_f[\vec{0},0,\vec{t}_{i,b}]\cdot(1-r_i) \end{aligned} \tag{8}$$

  - For $i \in [m+1,2m]$: For $b \in H$, and for every $\vec{x} \in H^m$, $\vec{y}_{(i-m,m]} \in H^{2m-i}$, $\vec{y}_{[1,i-m)} \in H^{i-m-1}$, define $\vec{t}_{i,b} = (\vec{y}_{(i-m,m]},\vec{x},\vec{y}_{[1,i-m)},b,\vec{y}_{(i-m,m]}) \in H^{4m-i}$ and do:

$$\begin{aligned} f(r_{[1,i)},\mathtt{W}_{i-m},\vec{t}_{i,b}) &\leftarrow \mathtt{W}_{i-m}\cdot \boldsymbol{T}_f[\vec{0},1,\vec{t}_{i,b}] + (1-\mathtt{W}_{i-m})\cdot \boldsymbol{T}_f[\vec{0},0,\vec{t}_{i,b}] \\ \boldsymbol{T}_f[\vec{0},0,\vec{t}_{i,b}] &\leftarrow r_i\cdot \boldsymbol{T}_f[\vec{0},1,\vec{t}_{i,b}] + (1-r_i)\cdot \boldsymbol{T}_f[\vec{0},0,\vec{t}_{i,b}] \end{aligned} \tag{9}$$

- Let $\mathcal{F}$ contain all polynomials in $R_A[\mathtt{U}_i]_{0,\leq 1}$ (resp. $R_A[\mathtt{W}_i]_{\leq 1,0}$) defined at Equation (8) (resp. Equation (9)) throughout the execution.

Fig. 3. Evaluations of toast multi-linear polynomials prior to sum-check.

$\vec{\mathtt{X}}$ variables (Steps 2-6). In this phase, rather than reasoning about $f \in R_A[\vec{\mathtt{U}},\vec{\mathtt{W}},\vec{\mathtt{X}},\vec{\mathtt{Y}}]_{\leq 2,\leq 2}$ from Equation (7), we look at its constituent polynomials ($\widehat{\mathtt{mult}_{\mathtt{L}}}$, $\widehat{\mathtt{add}_{\mathtt{L}}}$, $\hat{V}_L$, $\widehat{\mathtt{mult}_{\mathtt{R}}}$, $\widehat{\mathtt{add}_{\mathtt{R}}}$, $\hat{V}_R$) separately. Dealing with non-commutative rings is the main reason for the different algorithms in these steps, compared with the simpler description in Libra [XZZ+19]. Whereas in Libra expressions of the form $\sum_{\vec{x},\vec{y}\in H^m} \mathtt{wp}(\vec{g},\vec{x},\vec{y}) f_2(\vec{x}) f_3(\vec{y})$ are rewritten as $\sum_{\vec{x}\in H^m} f_2(\vec{x})\cdot h_{\vec{g}}(\vec{x})$, where $h_{\vec{g}}(\vec{x}) = \sum_{\vec{y}\in H^m} \mathtt{wp}(\vec{g},\vec{x},\vec{y}) f_3(\vec{y})$, we cannot assume this to be possible in our setting, since $f_2(\vec{x}) \in R$ might not commute with $\mathtt{wp}(\vec{g},\vec{x},\vec{y})$.

Instead, we start by using the algorithm `SetupX` (Figure 7), which substitutes the $\vec{\mathtt{Z}},\vec{\mathtt{U}},\vec{\mathtt{W}}$ variables in the LUTs of $\widehat{\mathtt{mult}_{\mathtt{L}}}$, $\widehat{\mathtt{add}_{\mathtt{L}}}$, $\widehat{\mathtt{mult}_{\mathtt{R}}}$ and $\widehat{\mathtt{add}_{\mathtt{R}}}$ with their corresponding challenges. Next, applying `Function_Evaluations` (Figure 5) to the (updated) LUTs, we can produce LMLEs in the $\vec{\mathtt{X}}$ variables for $\hat{V}_L$ (in Step 3) and $\widehat{\mathtt{mult}_{\mathtt{L}}}$, $\widehat{\mathtt{add}_{\mathtt{L}}}$ (which happens within `Sumcheck_X_Left`). Given two multi-linear polynomials $f(\mathtt{X}), g(\mathtt{X})$, we know that we can compute the sum-check protocol

Algorithm $\texttt{Sumcheck\_}\{\texttt{U},\texttt{W}\}(f, \boldsymbol{T}_f, r_1, \ldots, r_{2m})$

Input: $f \in R_A[\vec{\texttt{U}}, \vec{\texttt{W}}, \vec{\texttt{X}}, \vec{\texttt{Y}}]_{\leq 2,\leq 2}$ from Equation (7), initial lookup table $\boldsymbol{T}_f$, random challenges $\vec{r} = (r_1, \ldots, r_{2m}) \in A^{2m}$.
Output: First $2m$ sumcheck messages for f.

- $\mathcal{F} \leftarrow \texttt{Function\_Evaluations\_}\{\texttt{U},\texttt{W}\}(f, \boldsymbol{T}_f, r_1, \ldots, r_{2m})$
- For $i \in [1, m]$ and $b \in H$, define $\vec{t}_{i,b} = (\vec{x}_{(i,m]}, \vec{y}, \vec{x}_{[1,i)}, b, \vec{x}_{(i,m]}, \vec{y}) \in H^{4m-i}$ for every $\vec{y} \in H^m$, $\vec{x}_{(i,m]} \in H^{m-i}$, $\vec{x}_{[1,i)} \in H^{i-1}$. Compute and send:

$$g_{i,b}(\texttt{U}_i) = \sum_{\vec{t}_{i,b} \in H^{4m-i}} f(r_1, \ldots, r_{i-1}, \texttt{U}_i, \vec{t}_{i,b}).$$

- For $i \in [m+1, 2m]$ and $b \in H$, define $\vec{t}_{i,b} = (\vec{y}_{(i-m,m]}, \vec{x}, \vec{y}_{[1,i-m)}, b, \vec{y}_{(i-m,m]}) \in H^{4m-i}$ for every $\vec{x} \in H^m$, $\vec{y}_{(i-m,m]} \in H^{2m-i}$, $\vec{y}_{[1,i-m)} \in H^{i-m-1}$. Compute and send:

$$g_{i,b}(\texttt{W}_{i-m}) = \sum_{\vec{t}_{i,b} \in H^{4m-i}} f(r_1, \ldots, r_{i-1}, \texttt{W}_{i-m}, \vec{t}_{i,b}).$$

- Return $\{g_{i,b}(\texttt{U}_i)\}_{b \in H, i \in [1,m]}$, $\{g_{i,b}(\texttt{W}_{i-m})\}_{b \in H, i \in [m+1,2m]}$.

Fig. 4. Sum-check polynomials for the block of $\vec{\texttt{U}}, \vec{\texttt{W}}$ variables.

on their product $f(\texttt{X}) \cdot g(\texttt{X})$ in linear time [Tha13]. That is what we do in algorithms `Sumcheck_X_Left` (Figure 8) and `Sumcheck_X_Right` (Figure 9), where we compute, in linear time and without reordering its terms, the sum-check messages for $\sum_{\vec{x},\vec{y} \in H^m} \texttt{wp}(\vec{g}, \vec{x}, \vec{y}) f_2(\vec{x}) f_3(\vec{y})$ corresponding to the $\vec{\texttt{X}}$ variables. The key observation for the latter two algorithms is that, for $i \in [m]$, $\vec{x} \in H^{m-i}$ and $\texttt{wp} \in \{\widehat{\texttt{add}}_{\texttt{L}}, \widehat{\texttt{mult}}_{\texttt{L}}, \widehat{\texttt{add}}_{\texttt{R}}, \widehat{\texttt{mult}}_{\texttt{R}}\}$, the set

$$\mathcal{N}_{\vec{x}}^i = \{\vec{y} \in H^m : \exists \vec{z} \in H^m, (x_1, \ldots, x_i) \in H^i \ s.t. \ \texttt{wp}(\vec{z}, (x_1, \ldots, x_i), \vec{x}, \vec{y}) \neq 0\},$$

is s.t. $\sum_{\vec{x} \in H^{m-i}} |\mathcal{N}_{\vec{x}}^i| \in O(2^{m-i})$. We exploit the sparseness of our wiring predicates to keep an $O(2^m)$-time prover without reordering the terms of Eq. (7).

$\vec{\texttt{Y}}$ variables (Steps 7-8). `Setup_Y` (Figure 10) substitutes the $\vec{\texttt{X}}$ variables with $\vec{r}_{[2m+1,3m]} \in A^m$ in the LUTs of $\widehat{\texttt{mult}}_{\texttt{L}}, \widehat{\texttt{add}}_{\texttt{L}}$, so that $\mathcal{P}$ obtains values $\widehat{\texttt{add}}_{\texttt{L}}(\vec{g}, \vec{r}_{[m+1,2m]}, \vec{r}_{[2m+1,3m]})$ and $\widehat{\texttt{mult}}_{\texttt{L}}(\vec{g}, \vec{r}_{[m+1,2m]}, \vec{r}_{[2m+1,3m]})$. Applying `Function_Evaluations` (Figure 5) to the LUT of $\hat{V}_R$ and the LUTs of $\widehat{\texttt{mult}}_{\texttt{R}}$ and $\widehat{\texttt{add}}_{\texttt{R}}$ (which were previously updated in `SetupX`, Figure 7), we can produce the different RMLEs in the $\vec{\texttt{Y}}$ variables that are required for the execution of `Sumcheck_Y` (Figure 11): For $i \in [m]$, $\vec{y} \in H^{m-i}$, polynomials $\hat{V}_R(\vec{r}_{[3m+1,3m+i-1]}, \texttt{Y}_i, \vec{y})$, $\widehat{\texttt{add}}_{\texttt{R}}(\vec{r}_{[3m+1,3m+i-1]}, \texttt{Y}_i, \vec{y})$ and $\widehat{\texttt{mult}}_{\texttt{R}}(\vec{r}_{[3m+1,3m+i-1]}, \texttt{Y}_i, \vec{y})$.

Algorithm $\texttt{Function\_Evaluations}(f, \boldsymbol{T}_f, r_1, \ldots, r_m)$

Input: Lookup table $\boldsymbol{T}_f$ corresponding to either $f \in R_A[\mathtt{X}_1, \ldots, \mathtt{X}_m]_{\leq 1,0}$ or $f \in R_A[\mathtt{Y}_1, \ldots, \mathtt{Y}_m]_{0,\leq 1}$, random challenges $\vec{r} = (r_1, \ldots, r_m) \in A^m$.
Output: Polynomials $f(r_1, \ldots, r_{i-1}, \mathtt{X}_i, \vec{b}) \in R_A[\mathtt{X}_i]$ (or $f(r_1, \ldots, r_{i-1}, \mathtt{Y}_i, \vec{b}) \in R_A[\mathtt{Y}_i]$) for $i \in [1, m]$ and $\vec{b} \in \{0,1\}^{m-i}$.

- For $i = 1, \ldots, m$ let $\vec{0}$ be the length-$(i-1)$ zero vector and do:
  - For $\vec{b} = (b_{m-i}, \ldots, b_1) \in H^{m-i}$ do:
    - If $f \in R_A[\mathtt{Y}_1, \ldots, \mathtt{Y}_m]_{0,\leq 1}$, define:

$$f(r_1, \ldots, r_{i-1}, \mathtt{Y}_i, \vec{b}) \leftarrow \big(\boldsymbol{T}_f[\vec{0}, 1, \vec{b}] - \boldsymbol{T}_f[\vec{0}, 0, \vec{b}]\big) \cdot \mathtt{Y}_i + \boldsymbol{T}_f[\vec{0}, 0, \vec{b}] \quad (10)$$
$$\boldsymbol{T}_f[\vec{0}, 0, \vec{b}] \leftarrow \big(\boldsymbol{T}_f[\vec{0}, 1, \vec{b}] - \boldsymbol{T}_f[\vec{0}, 0, \vec{b}]\big) \cdot r_i + \boldsymbol{T}_f[\vec{0}, 0, \vec{b}]$$

    - Else (i.e. if $f \in R_A[\mathtt{X}_1, \ldots, \mathtt{X}_m]_{\leq 1,0}$), define:

$$f(r_1, \ldots, r_{i-1}, \mathtt{X}_i, \vec{b}) \leftarrow \mathtt{X}_i \cdot \big(\boldsymbol{T}_f[\vec{0}, 1, \vec{b}] - \boldsymbol{T}_f[\vec{0}, 0, \vec{b}]\big) + \boldsymbol{T}_f[\vec{0}, 0, \vec{b}] \quad (11)$$
$$\boldsymbol{T}_f[\vec{0}, 0, \vec{b}] \leftarrow r_i \cdot \big(\boldsymbol{T}_f[\vec{0}, 1, \vec{b}] - \boldsymbol{T}_f[\vec{0}, 0, \vec{b}]\big) + \boldsymbol{T}_f[\vec{0}, 0, \vec{b}]$$

- Let $\mathcal{F}$ contain all polynomials in $R_A[\mathtt{X}_i]_{\leq 1,0}$ (resp. $R_A[\mathtt{Y}_i]_{0,\leq 1}$) defined at Equation (11) (resp. Equation (10)) throughout the execution.

Fig. 5. Evaluations of toast multi-linear polynomials for sum-check.

Algorithm $\texttt{Precompute}(g_1, \ldots, g_\ell)$

Input: Random challenge $\vec{g} = (g_1, \ldots, g_\ell) \in A^\ell$.
Output: Lookup table $\{\boldsymbol{T}_{\vec{g}}[\vec{b}]\}_{\vec{b} \in \{0,1\}^\ell}$ containing the evaluations of $I(\vec{g}, \vec{b}) = \prod_{i=1}^{m} \big(g_i \cdot b_i + (1 - g_i) \cdot (1 - b_i)\big)$.

- Set $\boldsymbol{T}_{\vec{g}}[\vec{0}] \leftarrow (1 - g_1)$ and $\boldsymbol{T}_{\vec{g}}[0, \ldots, 0, 1] \leftarrow g_1$.
- For $i = 1, \ldots, \ell - 1$, do:
  - For $(b_i, \ldots, b_1) \in \{0,1\}^i$, do:
    - $\boldsymbol{T}_{\vec{g}}[\vec{0}, 0, b_i, \ldots, b_1] \leftarrow \boldsymbol{T}_{\vec{g}}[\vec{0}, b_i, \ldots, b_1] \cdot (1 - g_{i+1})$.
    - $\boldsymbol{T}_{\vec{g}}[\vec{0}, 1, b_i, \ldots, b_1] \leftarrow \boldsymbol{T}_{\vec{g}}[\vec{0}, b_i, \ldots, b_1] \cdot g_{i+1}$.

Fig. 6. Computing LUT for identity polynomial evaluated at a challenge.

Algorithm $\texttt{Setup\_X}(f_1, \boldsymbol{T}_{f_1}, f_2, \boldsymbol{T}_{f_2}, f_3, \boldsymbol{T}_{f_3}, f_4, \boldsymbol{T}_{f_4}, \vec{\chi}, \vec{\psi}, \vec{r})$

Input: Multi-linear $f_1(z,x,y), f_2(z,x,y) \in R_A[\vec{\mathtt{X}}, \vec{\mathtt{W}}, \vec{\mathtt{Z}}]_{\leq 1,0}$, $f_3(z,x,y), f_4(z,x,y) \in R_A[\vec{\mathtt{Y}}, \vec{\mathtt{U}}, \vec{\mathtt{Z}}]_{\leq 1,0}$ and their initial look-up tables. Random challenges[a] $\vec{\chi}, \vec{\psi} \in A^m$, $\vec{r} \in A^{2m}$.

Output: Look-up tables $\boldsymbol{T}_{f_i}$ for the block of $\vec{\mathtt{X}}$ variables.

- $\boldsymbol{T}_{\vec{\chi}}[\vec{z}] \leftarrow \texttt{Precompute}(\vec{\chi})$.
- $\boldsymbol{T}_{\vec{\psi}}[\vec{z}] \leftarrow \texttt{Precompute}(\vec{\psi})$.
- $\boldsymbol{T}_{\vec{r}_{[1,m]}}[\vec{x}] \leftarrow \texttt{Precompute}(\vec{r}_{[1,m]})$.
- $\boldsymbol{T}_{\vec{r}_{[m+1,2m]}}[\vec{y}] \leftarrow \texttt{Precompute}(\vec{r}_{[m+1,2m]})$.
- $\forall \vec{x}, \vec{y} \in \{0,1\}^m$, set $\boldsymbol{T}_{f_1}[\vec{x}] = \boldsymbol{T}_{f_2}[\vec{x}] = \boldsymbol{T}_{f_3}[\vec{y}] = \boldsymbol{T}_{f_4}[\vec{y}] = 0$.
- For $i = 1, 2$ and for every $(\vec{z}, \vec{x}, \vec{y}) \in H^{3m}$ such that $f_i(\vec{z}, \vec{x}, \vec{y}) \neq 0$, do:

$$\boldsymbol{T}_{f_i}[\vec{x}] \leftarrow \boldsymbol{T}_{f_i}[\vec{x}] + \boldsymbol{T}_{\vec{\chi}}[\vec{z}] \cdot \boldsymbol{T}_{\vec{r}_{[m+1,2m]}}[\vec{y}] \cdot f_i(\vec{z}, \vec{x}, \vec{y}).$$

- For $i = 3, 4$ and for every $(\vec{z}, \vec{x}, \vec{y}) \in H^{3m}$ such that $f_i(\vec{z}, \vec{x}, \vec{y}) \neq 0$, do:

$$\boldsymbol{T}_{f_i}[\vec{y}] \leftarrow \boldsymbol{T}_{f_i}[\vec{y}] + f_i(\vec{z}, \vec{x}, \vec{y}) \cdot \boldsymbol{T}_{\vec{\psi}}[\vec{z}] \cdot \boldsymbol{T}_{\vec{r}_{[1,m]}}[\vec{x}].$$

- Return $\boldsymbol{T}_{f_1}[x], \boldsymbol{T}_{f_2}[x], \boldsymbol{T}_{f_3}[y], \boldsymbol{T}_{f_4}[y]$.

[a] For a shorter write-up, we describe this algorithm as if $\vec{z}, \vec{x}, \vec{y} \in \{0,1\}^m$. In practice, since $\vec{z}$ comes from a different layer, it might have different length.

Fig. 7. Substituting $\vec{\mathtt{Z}}, \vec{\mathtt{U}}, \vec{\mathtt{W}}$ in LUTs with their corresponding challenges.

Algorithm

$\texttt{Sumcheck\_X\_Left}(\widehat{\texttt{mult}}_{\texttt{L}}, \boldsymbol{T}_{\widehat{\texttt{mult}}_{\texttt{L}}}(\vec{x}), \widehat{\texttt{add}}_{\texttt{L}}, \boldsymbol{T}_{\widehat{\texttt{add}}_{\texttt{L}}}(\vec{x}), \mathcal{F}_{\hat{V}_L}, \hat{V}_R, \boldsymbol{T}_{\hat{V}_R}(\vec{y}), \vec{r}_{[2m+1,3m]})$

Input: Parse $\vec{\texttt{X}} = (\texttt{X}_1, \ldots, \texttt{X}_m)$ and $\vec{\texttt{Y}} = (\texttt{Y}_1, \ldots, \texttt{Y}_m)$. Toast polynomials $\widehat{\texttt{mult}}_{\texttt{L}}(\vec{\chi}, \vec{r}_{[m+1,2m]}, \vec{\texttt{X}}), \widehat{\texttt{add}}_{\texttt{L}}(\vec{\chi}, \vec{r}_{[m+1,2m]}, \vec{\texttt{X}}), \hat{V}_L(\vec{\texttt{X}}) \in R_A[\vec{\texttt{X}}]_{\leq 1,0}$ and $\hat{V}_R(\vec{\texttt{Y}}) \in R_A[\vec{\texttt{Y}}]_{0,\leq 1}$, given by their lookup tables $\boldsymbol{T}_{\widehat{\texttt{mult}}_{\texttt{L}}}(x), \boldsymbol{T}_{\widehat{\texttt{add}}_{\texttt{L}}}(x), \boldsymbol{T}_{\hat{V}_R}(y)$ containing all evaluations at H^m. Random challenges $\vec{r}_{[2m+1,3m]} \in A^m$ and table $\mathcal{F}_{\hat{V}_L} \leftarrow \texttt{Function\_Evaluations}(\hat{V}_L, \boldsymbol{T}_{\hat{V}_L}, r_{2m+1}, \ldots, r_{3m})$.

Output: $2m$ partial sumcheck messages, half for $\sum_{\vec{x},\vec{y}\in H^m} g^{\texttt{mult}_{\texttt{L}}}_{2m+i}(\vec{x},\vec{y})$ and half for $\sum_{\vec{x},\vec{y}\in H^m} g^{\texttt{add}_{\texttt{L}}}_{2m+i}(\vec{x},\vec{y})$. Each message is a polynomial in $R_A[\texttt{X}_i]_{\leq 2,0}$.

- $\mathcal{F}_{\widehat{\texttt{mult}}_{\texttt{L}}} \leftarrow \texttt{Function\_Evaluations}(\widehat{\texttt{mult}}_{\texttt{L}}, \boldsymbol{T}_{\widehat{\texttt{mult}}_{\texttt{L}}}, r_{2m+1}, \ldots, r_{3m})$.
- $\mathcal{F}_{\widehat{\texttt{add}}_{\texttt{L}}} \leftarrow \texttt{Function\_Evaluations}(\widehat{\texttt{add}}_{\texttt{L}}, \boldsymbol{T}_{\widehat{\texttt{add}}_{\texttt{L}}}, r_{2m+1}, \ldots, r_{3m})$.
- Compute $Y = \sum_{\vec{y}\in H^m} \hat{V}_R(\vec{y})$ from $\boldsymbol{T}_{\hat{V}_R}(\vec{y})$ and store it for the next steps.
- For $i \in [m]$, compute as follows:

$$g^{\texttt{mult}_{\texttt{L}}}_{2m+i}(\texttt{X}_i) = \sum_{\vec{x}\in H^{m-i}} \widehat{\texttt{mult}}_{\texttt{L}}(\vec{r}_{[2m+1,2m+i-1]}, \texttt{X}_i, \vec{x}) \cdot \hat{V}_L(\vec{r}_{[2m+1,2m+i-1]}, \texttt{X}_i, \vec{x}) \cdot Y.$$

$$g^{\texttt{add}_{\texttt{L}}}_{2m+i}(\texttt{X}_i) = \sum_{\vec{x}\in H^{m-i}} \widehat{\texttt{add}}_{\texttt{L}}(\vec{r}_{[2m+1,2m+i-1]}, \texttt{X}_i, \vec{x}) \cdot \Big(\hat{V}_L(\vec{r}_{[2m+1,2m+i-1]}, \texttt{X}_i, \vec{x}) + Y \Big).$$

- Return each polynomial $\{g^{\texttt{mult}_{\texttt{L}}}_{2m+1}(\texttt{X}_1), g^{\texttt{add}_{\texttt{L}}}_{2m+1}(\texttt{X}_1), \ldots, g^{\texttt{mult}_{\texttt{L}}}_{3m}(\texttt{X}_m), g^{\texttt{add}_{\texttt{L}}}_{3m}(\texttt{X}_m)\}$.

Fig. 8. Sumcheck polynomials for $\vec{\texttt{X}}$ variables and "$\hat{V}^{(i)}_L$-side" of Equation (7).

Algorithm

$\texttt{Sumcheck\_X\_Right}(\widehat{\texttt{mult}}_{\texttt{R}}, \boldsymbol{T}_{\widehat{\texttt{mult}}_{\texttt{R}}}(\vec{y}), \widehat{\texttt{add}}_{\texttt{R}}, \boldsymbol{T}_{\widehat{\texttt{add}}_{\texttt{R}}}(\vec{y}), \mathcal{F}_{\hat{V}_L}, \hat{V}_R, \boldsymbol{T}_{\hat{V}_R}(\vec{y}), \vec{r}_{[2m+1,3m]})$

Input: Parse $\vec{\texttt{X}} = (\texttt{X}_1, \ldots, \texttt{X}_m)$ and $\vec{\texttt{Y}} = (\texttt{Y}_1, \ldots, \texttt{Y}_m)$. Table $\mathcal{F}_{\hat{V}_L}$ with all evaluations of $\hat{V}_L(\vec{\texttt{X}}) \in R_A[\vec{\texttt{X}}]_{\leq 1,0}$ in H^m. Toast polynomials $\widehat{\texttt{mult}}_{\texttt{R}}(\vec{\psi}, \vec{r}_{[1,m]}, \vec{\texttt{Y}}), \widehat{\texttt{add}}_{\texttt{R}}(\vec{\psi}, \vec{r}_{[1,m]}, \vec{\texttt{Y}}), \hat{V}_R(\vec{\texttt{Y}}) \in R_A[\vec{\texttt{Y}}]_{0,\leq 1}$ given by their lookup tables $\boldsymbol{T}_{\widehat{\texttt{mult}}_{\texttt{R}}}(\vec{y}), \boldsymbol{T}_{\widehat{\texttt{add}}_{\texttt{R}}}(\vec{y}), \boldsymbol{T}_{\hat{V}_R}(\vec{y})$, containing all evaluations at H^m. Random challenges $\vec{r}_{[2m+1,3m]} \in A^m$ and table $\mathcal{F}_{\hat{V}_L} \leftarrow \texttt{Function\_Evaluations}(\hat{V}_L, \boldsymbol{T}_{\hat{V}_L}, r_{2m+1}, \ldots, r_{3m})$.

Output: $2m$ partial sumcheck messages, half for $\sum_{\vec{x},\vec{y}\in H^m} g^{\texttt{mult}_{\texttt{R}}}_{2m+i}(\vec{x},\vec{y})$ and half for $\sum_{\vec{x},\vec{y}\in H^m} g^{\texttt{add}_{\texttt{R}}}_{2m+i}(\vec{x},\vec{y})$. Each message is a polynomial in $R_A[\texttt{X}_i]_{\leq 1,0}$.

- For $i \in [m]$, compute $g^{\texttt{mult}_{\texttt{R}}}_{2m+i} \in R_A[\texttt{X}_i]_{\leq 1,0}$ as follows. Notice $\sum_{\vec{y}\in H^m} \hat{V}_R(\vec{y}) \cdot \widehat{\texttt{mult}}_{\texttt{R}}(\vec{y})$ can be computed once and in time $O(2^m)$ from $\boldsymbol{T}_{\hat{V}_R}(\vec{y})$ and $\boldsymbol{T}_{\widehat{\texttt{mult}}_{\texttt{R}}}(\vec{y})$ for all the steps.

$$g^{\texttt{mult}_{\texttt{R}}}_{2m+i}(\texttt{X}_i) = \sum_{\vec{x}\in H^{m-i}} \hat{V}_L(\vec{r}_{[2m+1,2m+i-1]}, \texttt{X}_i, \vec{x}) \cdot \Big(\sum_{\vec{y}\in H^m} \hat{V}_R(\vec{y}) \cdot \widehat{\texttt{mult}}_{\texttt{R}}(\vec{y}) \Big).$$

- For $i \in [m]$, compute $g^{\texttt{add}_{\texttt{R}}}_{2m+i} \in R_A[\texttt{X}_i]_{\leq 1,0}$ as follows. First, compute $\sum_{\vec{y}\in H^m} \widehat{\texttt{add}}_{\texttt{R}}(\vec{y})$. Next, compute $\sum_{\vec{y}\in H^m} \hat{V}_R(\vec{y}) \cdot \widehat{\texttt{add}}_{\texttt{R}}(\vec{y})$. Given those, the next expression can be computed in $O(2^{m-i})$ time.

$$g^{\texttt{add}_{\texttt{R}}}_{2m+i}(\texttt{X}_i) = \sum_{\vec{x}\in H^{m-i}} \sum_{\vec{y}\in H^m} \Big(\hat{V}_L(\vec{r}_{[2m+1,2m+i-1]}, \texttt{X}_i, \vec{x}) + \hat{V}_R(\vec{y}) \Big) \cdot \widehat{\texttt{add}}_{\texttt{R}}(\vec{y}).$$

- Return each polynomial $\{g^{\texttt{mult}_{\texttt{R}}}_{2m+1}(\texttt{X}_1), g^{\texttt{add}_{\texttt{R}}}_{2m+1}(\texttt{X}_1), \ldots, g^{\texttt{mult}_{\texttt{R}}}_{3m}(\texttt{X}_m), g^{\texttt{add}_{\texttt{R}}}_{3m}(\texttt{X}_m)\}$.

Fig. 9. Sumcheck polynomials for $\vec{\texttt{X}}$ variables and "$\hat{V}^{(i)}_R$-side" of Equation (7).

Algorithm $\texttt{Setup\_Y}(\widehat{\texttt{mult}}_{\texttt{L}}, \boldsymbol{T}_{\widehat{\texttt{mult}}_{\texttt{L}}}(\vec{x}), \widehat{\texttt{add}}_{\texttt{L}}, \boldsymbol{T}_{\widehat{\texttt{add}}_{\texttt{L}}}(\vec{x}), \vec{r}_{[2m+1,3m]})$

Input: $\widehat{\texttt{mult}}_{\texttt{L}}(\vec{\chi}, \vec{r}_{[m+1,2m]}, \vec{\texttt{X}}), \widehat{\texttt{add}}_{\texttt{L}}(\vec{\chi}, \vec{r}_{[m+1,2m]}, \vec{\texttt{X}}) \in R_A[\vec{\texttt{X}}]_{\leq 1,0}$ and their look-up tables after $\texttt{Setup\_X}$ (Figure 7). Random challenge $\vec{r}_{[2m+1,3m]} \in A^m$.

Output: Values $\widehat{\texttt{mult}}_{\texttt{L}}(\vec{g}, \vec{r}_{[m+1,2m]}, \vec{r}_{[2m+1,3m]})$ and $\widehat{\texttt{add}}_{\texttt{L}}(\vec{g}, \vec{r}_{[m+1,2m]}, \vec{r}_{[2m+1,3m]})$.

- $\boldsymbol{T}_{\vec{r}_{[2m+1,3m]}}[\vec{x}] \leftarrow \texttt{Precompute}(\vec{r}_{[2m+1,3m]})$.
- Compute:

$$\widehat{\texttt{add}}_{\texttt{L}}(\vec{\chi}, \vec{r}_{[m+1,2m]}, \vec{r}_{[2m+1,3m]}) = \sum_{\vec{x}\in H} \boldsymbol{T}_{\vec{r}_{[2m+1,3m]}}[\vec{x}] \cdot \boldsymbol{T}_{\widehat{\texttt{add}}_{\texttt{L}}}[\vec{x}].$$

$$\widehat{\texttt{mult}}_{\texttt{L}}(\vec{\chi}, \vec{r}_{[m+1,2m]}, \vec{r}_{[2m+1,3m]}) = \sum_{\vec{x}\in H} \boldsymbol{T}_{\vec{r}_{[2m+1,3m]}}[\vec{x}] \cdot \boldsymbol{T}_{\widehat{\texttt{mult}}_{\texttt{L}}}[\vec{x}].$$

- Return $\widehat{\texttt{mult}}_{\texttt{L}}(\vec{g}, \vec{r}_{[m+1,2m]}, \vec{r}_{[2m+1,3m]})$ and $\widehat{\texttt{add}}_{\texttt{L}}(\vec{g}, \vec{r}_{[m+1,2m]}, \vec{r}_{[2m+1,3m]})$.

Fig. 10. Substituting $\vec{\texttt{X}}$ with $\vec{r}_{[2m+1,3m]} \in A^m$ in the LUTs of $\widehat{\texttt{mult}}_{\texttt{L}}, \widehat{\texttt{add}}_{\texttt{L}}$.

Algorithm `Sumcheck_Y`

$(\widehat{\texttt{mult}_{\texttt{R}}}, \boldsymbol{T}_{\widehat{\texttt{mult}_{\texttt{R}}}}(y), \widehat{\texttt{add}_{\texttt{R}}}, \boldsymbol{T}_{\widehat{\texttt{add}_{\texttt{R}}}}(y), \hat{V}_R, \boldsymbol{T}_{\hat{V}_R}(y), \hat{V}_L(\vec{r}_{[2m+1,3m]}), m_L, a_L, \vec{s}, \beta)$

Input: Toast polynomials $\widehat{\texttt{mult}_{\texttt{R}}}(\vec{\psi}, \vec{r}_{[1,m]}, \vec{\texttt{Y}}), \widehat{\texttt{add}_{\texttt{R}}}(\vec{\psi}, \vec{r}_{[1,m]}, \vec{\texttt{Y}}), \hat{V}_R(\vec{\texttt{Y}}) \in R_A[\vec{\texttt{Y}}]_{0,\leq 1}$ given by their lookup tables $\boldsymbol{T}_{\widehat{\texttt{mult}_{\texttt{R}}}}(\vec{y}), \boldsymbol{T}_{\widehat{\texttt{add}_{\texttt{R}}}}(\vec{y})$ (after the execution of `Setup_X` (Figure 7)) and $\boldsymbol{T}_{\hat{V}_R}(\vec{y})$. Values $m_L = \alpha \cdot \widehat{\texttt{mult}_{\texttt{L}}}(\vec{\chi}, \vec{r}_{[m+1,3m]})$ and $a_L = \alpha \cdot \widehat{\texttt{add}_{\texttt{L}}}(\vec{\chi}, \vec{r}_{[m+1,3m]})$. Random challenges $\vec{s} = \vec{r}_{[3m+1,4m]} \in A^m$.
Output: Last m sumcheck messages for Equation (7). Each message is a polynomial $g_{3m+i}(\texttt{Y}_i) \in R_A[\texttt{Y}_i]_{\leq 2,0}$.

- $\mathcal{F}_{\hat{V}_R} \leftarrow$ `Function_Evaluations`$(\hat{V}_R, \boldsymbol{T}_{\hat{V}_R}, s_1, \ldots, s_m)$.
- $\mathcal{F}_{\widehat{\texttt{add}_{\texttt{R}}}} \leftarrow$ `Function_Evaluations`$(\widehat{\texttt{add}_{\texttt{R}}}, \boldsymbol{T}_{\widehat{\texttt{add}_{\texttt{R}}}}, s_1, \ldots, s_m)$.
- $\mathcal{F}_{\widehat{\texttt{mult}_{\texttt{R}}}} \leftarrow$ `Function_Evaluations`$(\widehat{\texttt{mult}_{\texttt{R}}}, \boldsymbol{T}_{\widehat{\texttt{mult}_{\texttt{R}}}}, s_1, \ldots, s_m)$.
- For $i \in [m]$, compute $g_{3m+i}(\texttt{Y}_i) = (g^L_{3m+i}(\texttt{Y}_i) + g^R_{3m+i}(\texttt{Y}_i)) \in R_A[\texttt{Y}_i]_{0,\leq 2}$ as follows. Notice that given $\mathcal{F}_{\hat{V}_R}, \mathcal{F}_{\widehat{\texttt{add}_{\texttt{R}}}}, \mathcal{F}_{\widehat{\texttt{mult}_{\texttt{R}}}}$, computation takes $O(2^{m-i})$ time:

$$g^L_{3m+i}(\texttt{Y}_i) = a_L \cdot \hat{V}_L(\vec{r}_{[2m+1,3m]}) + \sum_{\vec{y} \in H^{m-i}} \Big(a_L \cdot \hat{V}_R(\vec{s}_{[1,i-1]}, \texttt{Y}_i, \vec{y}) + m_L \cdot \hat{V}_L(\vec{r}_{[2m+1,3m]}) \cdot \hat{V}_R(\vec{s}_{[1,i-1]}, \texttt{Y}_i, \vec{y}) \Big).$$

$$g^R_{3m+i}(\texttt{Y}_i) = \beta \cdot \Big(\sum_{\vec{y} \in H^{m-i}} \big(\hat{V}_L(\vec{r}_{[2m+1,3m]}) + \hat{V}_R(\vec{s}_{[1,i-1]}, \texttt{Y}_i, \vec{y}) \big) \cdot \widehat{\texttt{add}_{\texttt{R}}}(\vec{s}_{[1,i-1]}, \texttt{Y}_i, \vec{y}) + \hat{V}_L(\vec{r}_{[2m+1,3m]}) \cdot \hat{V}_R(\vec{s}_{[1,i-1]}, \texttt{Y}_i, \vec{y}) \cdot \widehat{\texttt{mult}_{\texttt{R}}}(\vec{s}_{[1,i-1]}, \texttt{Y}_i, \vec{y}) \Big).$$

- Return each polynomial $\{g_{3m+1}(\texttt{Y}_1), \ldots, g_{4m}(\texttt{Y}_m)\}$.

Fig. 11. Sumcheck polynomials for the block of $\vec{\texttt{Y}}$ variables
