5 Summary

2 Hierarchy Integrated Signature and Encryption
 • HISE from (Constrained) IBE
 • HISE from PKE and NIZKPoK (HI coversion)

3 Global Escrow Property

- Global Escrow PKE from PKE and NIZK (GE conversion)
- Global Escrow PKE from 3-party NIKE
- 4 Comparison and Experimentation

5 Summary

PKE+SIG

PKE and SIG are "workhorse" primitives that are typically used simultaneously to secure communication

- $PKE \Rightarrow$ protect confidentiality
- SIG \Rightarrow protect authenticity: data integrity & authenticated data source

Classical examples

- Secure communication software: PGP, WhatsApp
- Privacy-preserving cryptocurrency: Zcash, Zether, PGC
- A Subtle Point: Joint security (somewhat akin to UC)
 - \bullet EUF-CMA security for SIG: holds even in the presence of \mathcal{O}_{dec}
 - \bullet IND-CCA security for PKE: holds even in the presence of \mathcal{O}_{sign}

Two Pincipals When Using PKE and SIG

Key Separation vs. Key Reuse

Key Separation: Cartesian-Product Combined Public-Key Scheme

Engineering folklore: using different keypairs for different cryptographic operations

Pros

- joint security is immediate & construction is off-the-shelf
- \bullet naturally admits individual key escrow \rightsquigarrow achieve a balance between user's authenticity requirement and society's auditing requirement

Cons

- double key management complexity and certificate cost¹
- complicate the design of high-level protocol: tricky address derivation

 $^1 \mbox{Certificate costs}$ include but not limit to registration, issuing, storage, transmission, verification, and building/recurring fees.

Key Reuse: Integrated Signature and Encryption

Pros

- reduce key management complexity, certificate cost, and cryptographic footprint
- simplify the design of high-level protocol

Cons

- joint security is not immediate (consider textbook RSA) & require careful design
- does not admit individual key escrow
- does not admit classified protection of secret keys

Deployed in EMV standard, Ping Identity, Zether and PGC

Motivation

We are facing a dilemma between key reuse that brings performance benefit and key separation that supports individual key escrow.

Can we enable individual key escrow mechanism while retaining the merits of key reuse?

Background

2 Hierarchy Integrated Signature and Encryption

- HISE from (Constrained) IBE
- HISE from PKE and NIZKPoK (HI coversion)

3 Global Escrow Property

- Global Escrow PKE from PKE and NIZK (GE conversion)
- Global Escrow PKE from 3-party NIKE

4 Comparison and Experimentation

5 Summary

Hierarchy Integrated Signature and Encryption

- $\mathsf{Setup}(1^{\lambda}) \to pp$
- KeyGen $(1^{\lambda}) \rightarrow (pk, sk)$. pk serves as encryption and verification key; sk is the signing key, serving as master secret key.
- $\bullet~ \operatorname{Derive}(sk) \to dk$ used only for decryption
- $\bullet \; \operatorname{Enc}(pk,m) \to c$
- $\bullet \ \operatorname{Dec}(dk,c) \to m$
- $\bullet \; \operatorname{Sign}(sk,\tilde{m}) \to \sigma$
- $\bullet \ \operatorname{Vefy}(pk,\tilde{m},\sigma) \to 0/1$

Strong Joint Security

IND-CCA security in the presence of a signing oracle (unrestricted access)

$$\Pr \begin{bmatrix} pp \leftarrow \mathsf{Setup}(1^{\lambda}); \\ (pk, sk) \leftarrow \mathsf{KeyGen}(pp); \\ b = b': \quad (m_0, m_1) \leftarrow \mathcal{A}^{\mathcal{O}_{\mathsf{dec}}, \mathcal{O}_{\mathsf{sign}}}(pp, pk); \\ b \leftarrow \mathcal{A}^{\mathcal{O}_{\mathsf{dec}}, \mathcal{O}_{\mathsf{sign}}}(c^*); \end{bmatrix} - \frac{1}{2} \leq \mathsf{negl}(\lambda).$$

EUF-CMA security in the presence of a decryption key

$$\Pr\left[\begin{array}{ccc} pp \leftarrow \mathsf{Setup}(1^{\lambda}); \\ \mathsf{Vrfy}(pk, m^*, \sigma^*) = 1 \\ \wedge m^* \notin \mathcal{Q} \end{array} : \begin{array}{c} pp \leftarrow \mathsf{Setup}(1^{\lambda}); \\ (pk, sk) \leftarrow \mathsf{KeyGen}(pp); \\ dk \leftarrow \mathsf{Derive}(sk); \\ (m^*, \sigma^*) \leftarrow \mathcal{A}^{\mathcal{O}_{\mathsf{sign}}}(pp, pk, \underline{dk}); \end{array}\right] \leq \mathsf{negl}(\lambda).$$

Application of HISE

Merit of HISE

- compact public key size
- reduce key management complexity
- simplify the design and analysis of high-level protocols

suitable for scenarios that simultaneously require privacy, authenticity and key escrow

Zether/PGP

outsource costly operations e.g., expensive decryption

auditing

Application of HISE

Merit of HISE

- compact public key size
- reduce key management complexity
- simplify the design and analysis of high-level protocols

suitable for scenarios that simultaneously require privacy, authenticity and key escrow

Application of HISE

Merit of HISE

- compact public key size
- reduce key management complexity
- simplify the design and analysis of high-level protocols

suitable for scenarios that simultaneously require privacy, authenticity and key escrow

Background

Provide the second state of the s

• HISE from PKE and NIZKPoK (HI coversion)

3 Global Escrow Property

- Global Escrow PKE from PKE and NIZK (GE conversion)
- Global Escrow PKE from 3-party NIKE

4 Comparison and Experimentation

5 Summary

Starting Point: ISE from IBE

ISE from IBE does not lend itself to HISE

msk plays the role of both sk and $dk \sim does$ not satisfy strong joint security

HISE from Constrained IBE for Prefix Predicate

Main idea: msk acts as sk, secret keys for identities in I_1 as decryption key

Technical hurdle: decryption key should be short \sim we need a succinct representation for all secret keys for identites in $I_1 \Leftarrow$ constrained IBE for prefix predicates \Leftarrow BTE

Efficient Instantiation - HISE Scheme 1

The above generic construction from constrained IBE enjoys joint security in the standard model.

• constrained IBE is still less efficient

In applications where IND-CPA security suffice, or one is willing to accept IND-CCA security in the random oracle model, we have a simpler and more efficient construction of HISE from any IBE.

Background

Hierarchy Integrated Signature and Encryption HISE from (Constrained) IBE HISE from PKE and NIZKPoK (HI coversion)

3 Global Escrow Property

- Global Escrow PKE from PKE and NIZK (GE conversion)
- Global Escrow PKE from 3-party NIKE
- 4 Comparison and Experimentation

5 Summary

HISE from PKE and NIZKPoK (HI coversion)

Goal: add signing functionality to PKE in a generic manner

 \bullet bootstrap PKE in-use to HISE \rightsquigarrow enables a seamless upgrade

Idea: create hierarchical key structure via OWF

- picks $sk \stackrel{\mathsf{R}}{\leftarrow} \{0,1\}^n$ as signing key
- **2** maps sk to randomness r via uniform OWF: $F(sk) \rightarrow r$
- runs PKE.KeyGen $(r) \rightarrow (pk, dk)$

Figure: The hierarchical key structure

HISE from PKE and NIZKPoK (HI coversion)

The encryption component of HISE is simple: same as that of the underlying PKE.

But, we are facing the following technical hurdle when designing signature:

- sk is unstructured bit string, how to create the signing functionality?
- the signature should remain secure even in the presence of dk (partial leakage of sk) \Rightarrow strong joint security

Solution

- using general-purpose public-coin ZKPoK to prove knowledge of sk given pk
- ullet require $\mathsf{R}_{\mathsf{key}}$ to be leakage-resilient one-way w.r.t. leakage r and thus certainly dk
 - $\bullet\,$ minimum requirement on G: target-collision resistant

Strong joint security:

- \bullet SIG component: Sigma protocol for leakage-resilient one-way relation \rightsquigarrow leakage-resilient SIG
- PKE component: zero-knowledge property $\leadsto \mathcal{O}_{sign}$ is useless + uniformity of F admits security reduction to the underlying PKE

"Efficient" Instantiation - HISE Scheme 2

The above construction is still less practical for real world applications. The bottleneck lies at general-purpose ZKPoK.

• We left more efficient instantiation as an interesting open problem.

Background

2 Hierarchy Integrated Signature and Encryption
 • HISE from (Constrained) IBE
 • HISE from PKE and NIZKPoK (HI coversion)

3 Global Escrow Property

• Global Escrow PKE from PKE and NIZK (GE conversion)

- Global Escrow PKE from 3-party NIKE
- 4 Comparison and Experimentation

5 Summary

Motivation of Global Escrow

Motivating example: large-scale collaborative working Apps such as Slack is getting popular \rightsquigarrow encrypted communication may contain proprietary information

- employer may have the right to get access to all private communications for various reasons
 - naive solution: collect individual decryption key one by one \Rightarrow impractical and inefficient
- employees need to be assured that even a malicious employer cannot slander them by forging signatures for fabricated communications

We further expect global escrow property

- there is a "super" key that can decrypt any ciphertext under any public key
- signature remains secure even in the presence of the "super" key

To attain global escrow property for HISE in a generic manner, we first take a detour to revisit global escrow PKE.

Global Escrow PKE

Global escrow PKE: an escrow agent holds a global escrow decryption key that can decrypt ciphertexts encrypted under any public key

The state of the art of global escrow PKE is less satisfactory

- long overdue for formal definition and generic construction
- the only known practical scheme is the escrow ElGamal PKE proposed by Boneh and Franklin from bilinear maps

Formal Definition

Correctness: honestly generated CTs decrypting to the same result under edk and sk_r Consistency: no PPT adversary can generate an ill-formed CT decrypting different results under edk and sk_r

Failure attempts

- Identity-based encryption: does not directly lend itself to global escrow PKE (users must be able to generate keypairs themselves)
- Broadcast encryption: sender could be malicious especially when he has incentive to evade oversight

Background

2 Hierarchy Integrated Signature and Encryption
 • HISE from (Constrained) IBE
 • HISE from PKE and NIZKPoK (HI coversion)

Global Escrow Property

- Global Escrow PKE from PKE and NIZK (GE conversion)
- Global Escrow PKE from 3-party NIKE
- 4 Comparison and Experimentation

5 Summary

Global Escrow PKE from PKE and NIZK (GE conversion)

Give a generic approach to compile any PKE into global escrow PKE

- enrich the application scope of the Naor-Yung transform beyond CCA security
- achieve CCA security with no overhead

Efficient Instantiation - Global Escrow PKE Scheme 1

Choices of primitives

- PKE: ElGamal PKE in EC groups
- NIZK: Groth-Sahai proof in standard model or Sigma proof in random oracle model

Improvement

 When PKE satisfies the "randomness fusion" property [BMV16], we can safely reuse the randomness and then apply twisted Naor-Yung transform ⇒ better efficiency

plenty of PKE schemes from the DDH, quadratic residuosity, and subset sum assumptions satisfy randomness fusion property.

Background

2 Hierarchy Integrated Signature and Encryption
• HISE from (Constrained) IBE
• HISE from PKE and NIZKPoK (HI coversion)

Global Escrow Property

- Global Escrow PKE from PKE and NIZK (GE conversion)
- Global Escrow PKE from 3-party NIKE

5 Summary

Multiparty NIKE

- n = 2: Diffie-Hellman key exchange [DH76]
- n = 3: Joux's key exchange [Jou04] from bilinear maps
- n is any positive integer
 - Boneh and Silverberg [BS02] using multilinear maps
 - Alamati et al. [AMPR19] using composable input homomorphic weak PRF

Global Escrow PKE from 3-party NIKE

- security of NIZK (pseudorandomness of shared key k) \Rightarrow IND-CPA/CCA security
- PK is efficiently recognizable \Rightarrow consistency

Efficent Instantiation (First Attempt)

Joux's 3-party NIZK from symmetric pairing

Recover the only prior known scheme Boneh-Franklin escrow ElGamal PKE

- Setup (1^{λ}) : $edk \xleftarrow{\mathsf{R}} \mathbb{Z}_p$, $epk \leftarrow g^{edk}$.
- KeyGen(pp): $sk \xleftarrow{\mathsf{R}} \mathbb{Z}_p$, $pk \leftarrow g^{sk}$.
- $\operatorname{Enc}(pk,m)$: $sk_t \stackrel{\mathbb{R}}{\leftarrow} \mathbb{Z}_p$, $pk_t \leftarrow g^{sk_t}$; $k \leftarrow \operatorname{ShareKey}(sk_t, S = \{pk_t, pk, epk\})$, $c = (pk_t, m \oplus k)$
- $\mathsf{Dec}(sk,c)$: $k \leftarrow \mathsf{ShareKey}(sk, S = \{pk_t, pk, epk\}), m \leftarrow c_2 \oplus k.$
- $\mathsf{Dec}'(edk, c)$: $k \leftarrow \mathsf{ShareKey}(edk, S = \{pk_t, pk, epk\}), m \leftarrow c_2 \oplus k.$

Efficent Instantiation (Second Attempt)

The original Joux's protocol inherently relies on symmetric pairing

Second attempt to improve efficiency: adapt Joux's protocol with asymmetric pairing

Efficent Instantiation (Final Attempt) - Global Escrow PKE Scheme 2

New Global Escrow PKE

- Setup (1^{λ}) : $edk \xleftarrow{\mathsf{R}} \mathbb{Z}_p$, $epk = (g_1^{edk}, g_2^{edk})$ (type-A)
- KeyGen(pp): $sk \xleftarrow{\mathsf{R}} \mathbb{Z}_p$, $pk \leftarrow g_2^{sk}$ (type-B)

• Enc
$$(pk, m)$$
: $sk_t \leftarrow \mathbb{Z}_p$, $pk_t \leftarrow g_1^{sk_t}$ (type-C);
 $k \leftarrow \text{ShareKey}(sk_t, S = \{pk_t, pk, epk\})$, $c = (pk_t, m \oplus k)$

- $\mathsf{Dec}(sk,c)$: $k \leftarrow \mathsf{ShareKey}(sk, S = \{pk_t, pk, epk\}), m \leftarrow c_2 \oplus k$
- $\mathsf{Dec}'(edk, c)$: $k \leftarrow \mathsf{ShareKey}(edk, S = \{pk_t, pk, epk\}), m \leftarrow c_2 \oplus k$

Global Escrow HISE

Figure: Technology roadmap of global escrow HISE. The rectangles denote our newly introduced cryptographic schemes.

Efficient Instantiations of Global Escrow HISE

Applications of Global Escrow HISE

- The employer can perform efficient large-scale supervision over private communications with "super" key.
- The employees are assured that even a malicious boss of the "super" key cannot slander them by forging signatures for fabricated communications.

Background

2 Hierarchy Integrated Signature and Encryption
 • HISE from (Constrained) IBE
 • HISE from PKE and NIZKPoK (HI coversion)

3 Global Escrow Property

- Global Escrow PKE from PKE and NIZK (GE conversion)
- Global Escrow PKE from 3-party NIKE

4 Comparison and Experimentation

5 Summary

Comparison with Cartesian-Product CPK and ISE

Table: Comparison between CP-CPK, ISE, and our (global escrow) HISE

Schomo	strong	individual	global	key	certificate	
Scheme	joint security	escrow	escrow	reuse	cost	
CP-CPK [PSST11]	✓	1	X	×	$\times 2$	
ISE [PSST11]	×	×	X	1	$\times 1$	
HISE	✓	1	X	1	$\times 1$	
global escrow HISE	✓	1	1	1	$\times 1$	

For certificate cost, $\times 1$ (resp. $\times 2$) means the cost associated with one (resp. two) certificate(s). As aforementioned, certificate costs include but not limit to registration, issuing, storage, transmission, verification, and building/recurring fees. Take SSL certificate as an example, one certificate is roughly 1KB, takes roughly 200~300ms to transmit in WAN setting with 50Mbps network bandwidth and 8ms to verify. The monetary cost for an SSL certificate varies depending on features and business needs. While the cost of an SSL certificate for common usage is \$10~\$2000/year, the banks and large financial institutions could spend up to \$500,000/year on an SSL certificate with high-level security guranttee.

Experimental Results

Scheme	efficiency (ms) [# exp, #pairing]						sizes (bits) [# \mathbb{G} , # \mathbb{Z}_p]

Table: Efficiency comparison of CPK and our proposed (global escrow) HISE schemes

Performance of Cartesian product CPK and (global escrow) HISE schemes with 128-bit security level. $(\mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_T)$ refers to asymmetric pairing groups. \mathbb{G} refers to ordinary elliptic group. The symbol \oslash indicates that there is no corresponding algorithm. The symbol N/A indicates that the efficiency (or bandwidth) is hard to measure by algebra operations (or elements).

A Byproduct: Global Escrow PKE

Scheme	efficiency (ms) $[\# exp, \# pairing]$				sizes (bits) [$\#$ \mathbb{G} , $\#$ \mathbb{Z}_p]					
	Setup	KGen	Enc	Dec	Dec'	pp	edk	pk	sk	c
Boneh-Franklin	2.879	2.014	8.723	6.654	6.745	3072	256	1536	256	3072
escrow ElGamal PKE	[2, 0]	[1, 0]	[2, 1]	[1, 1]	[1, 1]	$2\mathbb{G}$	\mathbb{Z}_p	\mathbb{G}	\mathbb{Z}_p	$[\mathbb{G},\mathbb{G}_T]$
our proposed	0.243	0.058	0.680	0.579	0.586	2286	256	381	256	2286
global escrow PKE	[4, 0]	[1, 0]	[2, 1]	[1, 1]	[1, 1]	$[2\mathbb{G}_1, 2\mathbb{G}_2]$	\mathbb{Z}_p	\mathbb{G}_1	\mathbb{Z}_p	$[\mathbb{G}_2,\mathbb{G}_T]$

Table: Comparison of escrow ElGamal PKE [BF03] and our global escrow PKE

Performance of global escrow PKE schemes with 128-bit security level. $(\mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_T)$ refers to asymmetric pairing groups. $(\mathbb{G}, \mathbb{G}_T)$ refers to symmetric pairing groups. We report times for setup, key generation, encryption, and (escrow) decryption, as well as the sizes of public parameters pp, global escrow decryption key edk, public key pk, secret key sk, and ciphertext c.

$12\sim 30\times$ speed up

Our implementation is released on Github: https://github.com/yuchen1024/HISE

Background

2 Hierarchy Integrated Signature and Encryption
 • HISE from (Constrained) IBE
 • HISE from PKE and NIZKPoK (HI coversion)

3 Global Escrow Property

- Global Escrow PKE from PKE and NIZK (GE conversion)
- Global Escrow PKE from 3-party NIKE
- 4 Comparison and Experimentation

Summary

sweet balance

HISE (formal definition + generic constructions)

- reconcile the apparent conflict between key separation and key resue
- resolve the problem left open in Verheul [Ver01] at Eurocrypt 2001
- can be used as a drop-in replacement of PKE+SIG in scenarios that requires authenticity, confidentiality and auditibility simultaneously
- both users and authority have incentives to deploy

Global escrow PKE revisit (formal definition + generic constructions)

- indicate a new application of Naor-Yung paradigm
- establish a novel connection from 3-party NIKE
