EKE and OEKE design patterns

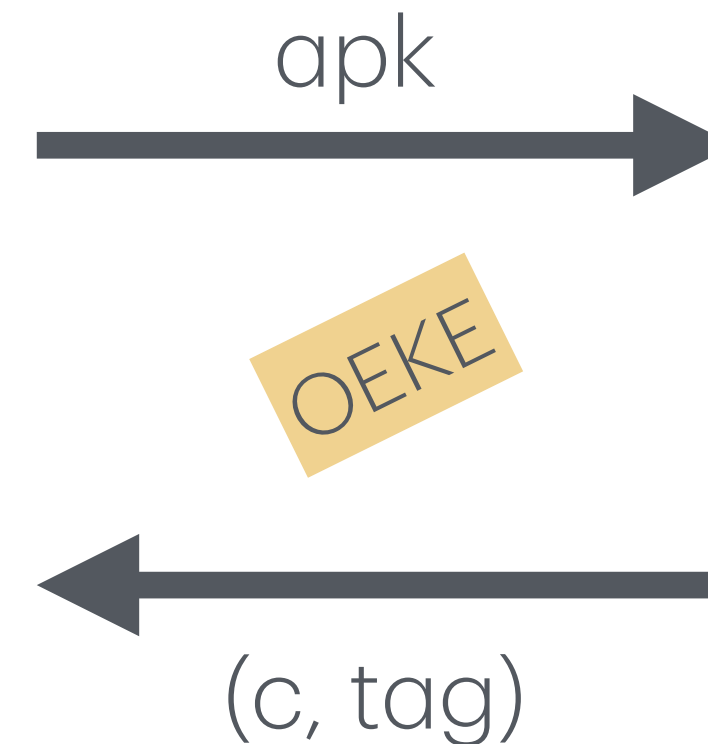

$(sk, pk) \leftarrow \text{KEM.Keygen}$
 $apk \leftarrow \text{IC.Enc}(pw_A, pk)$

$pk \leftarrow \text{IC.Dec}(pw_B, apk)$
 $(K, c) \leftarrow \text{KEM.Encaps}(pk)$
 $c^* \leftarrow \text{IC.Enc}(pw_B, c)$
 $key \leftarrow H(pk, apk, c, K, \dots)$

$c \leftarrow \text{IC.Dec}(pw_A, c^*)$
 $K \leftarrow \text{KEM.Decaps}(sk, c)$
 $key \leftarrow H(pk, apk, c, K, \dots)$

$(sk, pk) \leftarrow \text{KEM.Keygen}$
 $apk \leftarrow \text{IC.Enc}(pw_A, pk)$

$pk \leftarrow \text{IC.Dec}(pw_B, apk)$
 $(K, c) \leftarrow \text{KEM.Encaps}(pk)$
 $(key, \mathbf{tag}) \leftarrow H(pk, apk, c, K, \dots)$

$K \leftarrow \text{KEM.Decaps}(sk, c)$
 $(key, \mathbf{tag}') \leftarrow H(pk, apk, c, K, \dots)$
check if $\mathbf{tag} == \mathbf{tag}'$

EKE and OEKE design patterns

PAKE-KEM [PZ23]

CAKE [BCP+23]

$(sk, pk) \leftarrow \text{KEM.Keygen}$
 $apk \leftarrow \text{IC.Enc}(pw_A, pk)$

apk

EKE

$pk \leftarrow \text{IC.Dec}(pw_B, apk)$
 $(K, c) \leftarrow \text{KEM.Encaps}(pk)$
 $c^* \leftarrow \text{IC.Enc}(pw_B, c)$
 $key \leftarrow H(pk, apk, c, K, \dots)$

c^*

sPAKE [MRR20]

$c \leftarrow \text{IC.Dec}(pw_A, c^*)$
 $K \leftarrow \text{KEM.Decaps}(sk, c)$
 $key \leftarrow H(pk, apk, c, K, \dots)$

CHIC [this paper]

EKE-KEM [SGJ23]

$(sk, pk) \leftarrow \text{KEM.Keygen}$
 $apk \leftarrow \text{IC.Enc}(pw_A, pk)$

apk

OEKE

$pk \leftarrow \text{IC.Dec}(pw_B, apk)$
 $(K, c) \leftarrow \text{KEM.Encaps}(pk)$
 $(key, \mathbf{tag}) \leftarrow H(pk, apk, c, K, \dots)$

(c, \mathbf{tag})

OCAKE [BCP+23]

$K \leftarrow \text{KEM.Decaps}(sk, c)$
 $(key, \mathbf{tag}') \leftarrow H(pk, apk, c, K, \dots)$
 check if $\mathbf{tag} == \mathbf{tag}'$

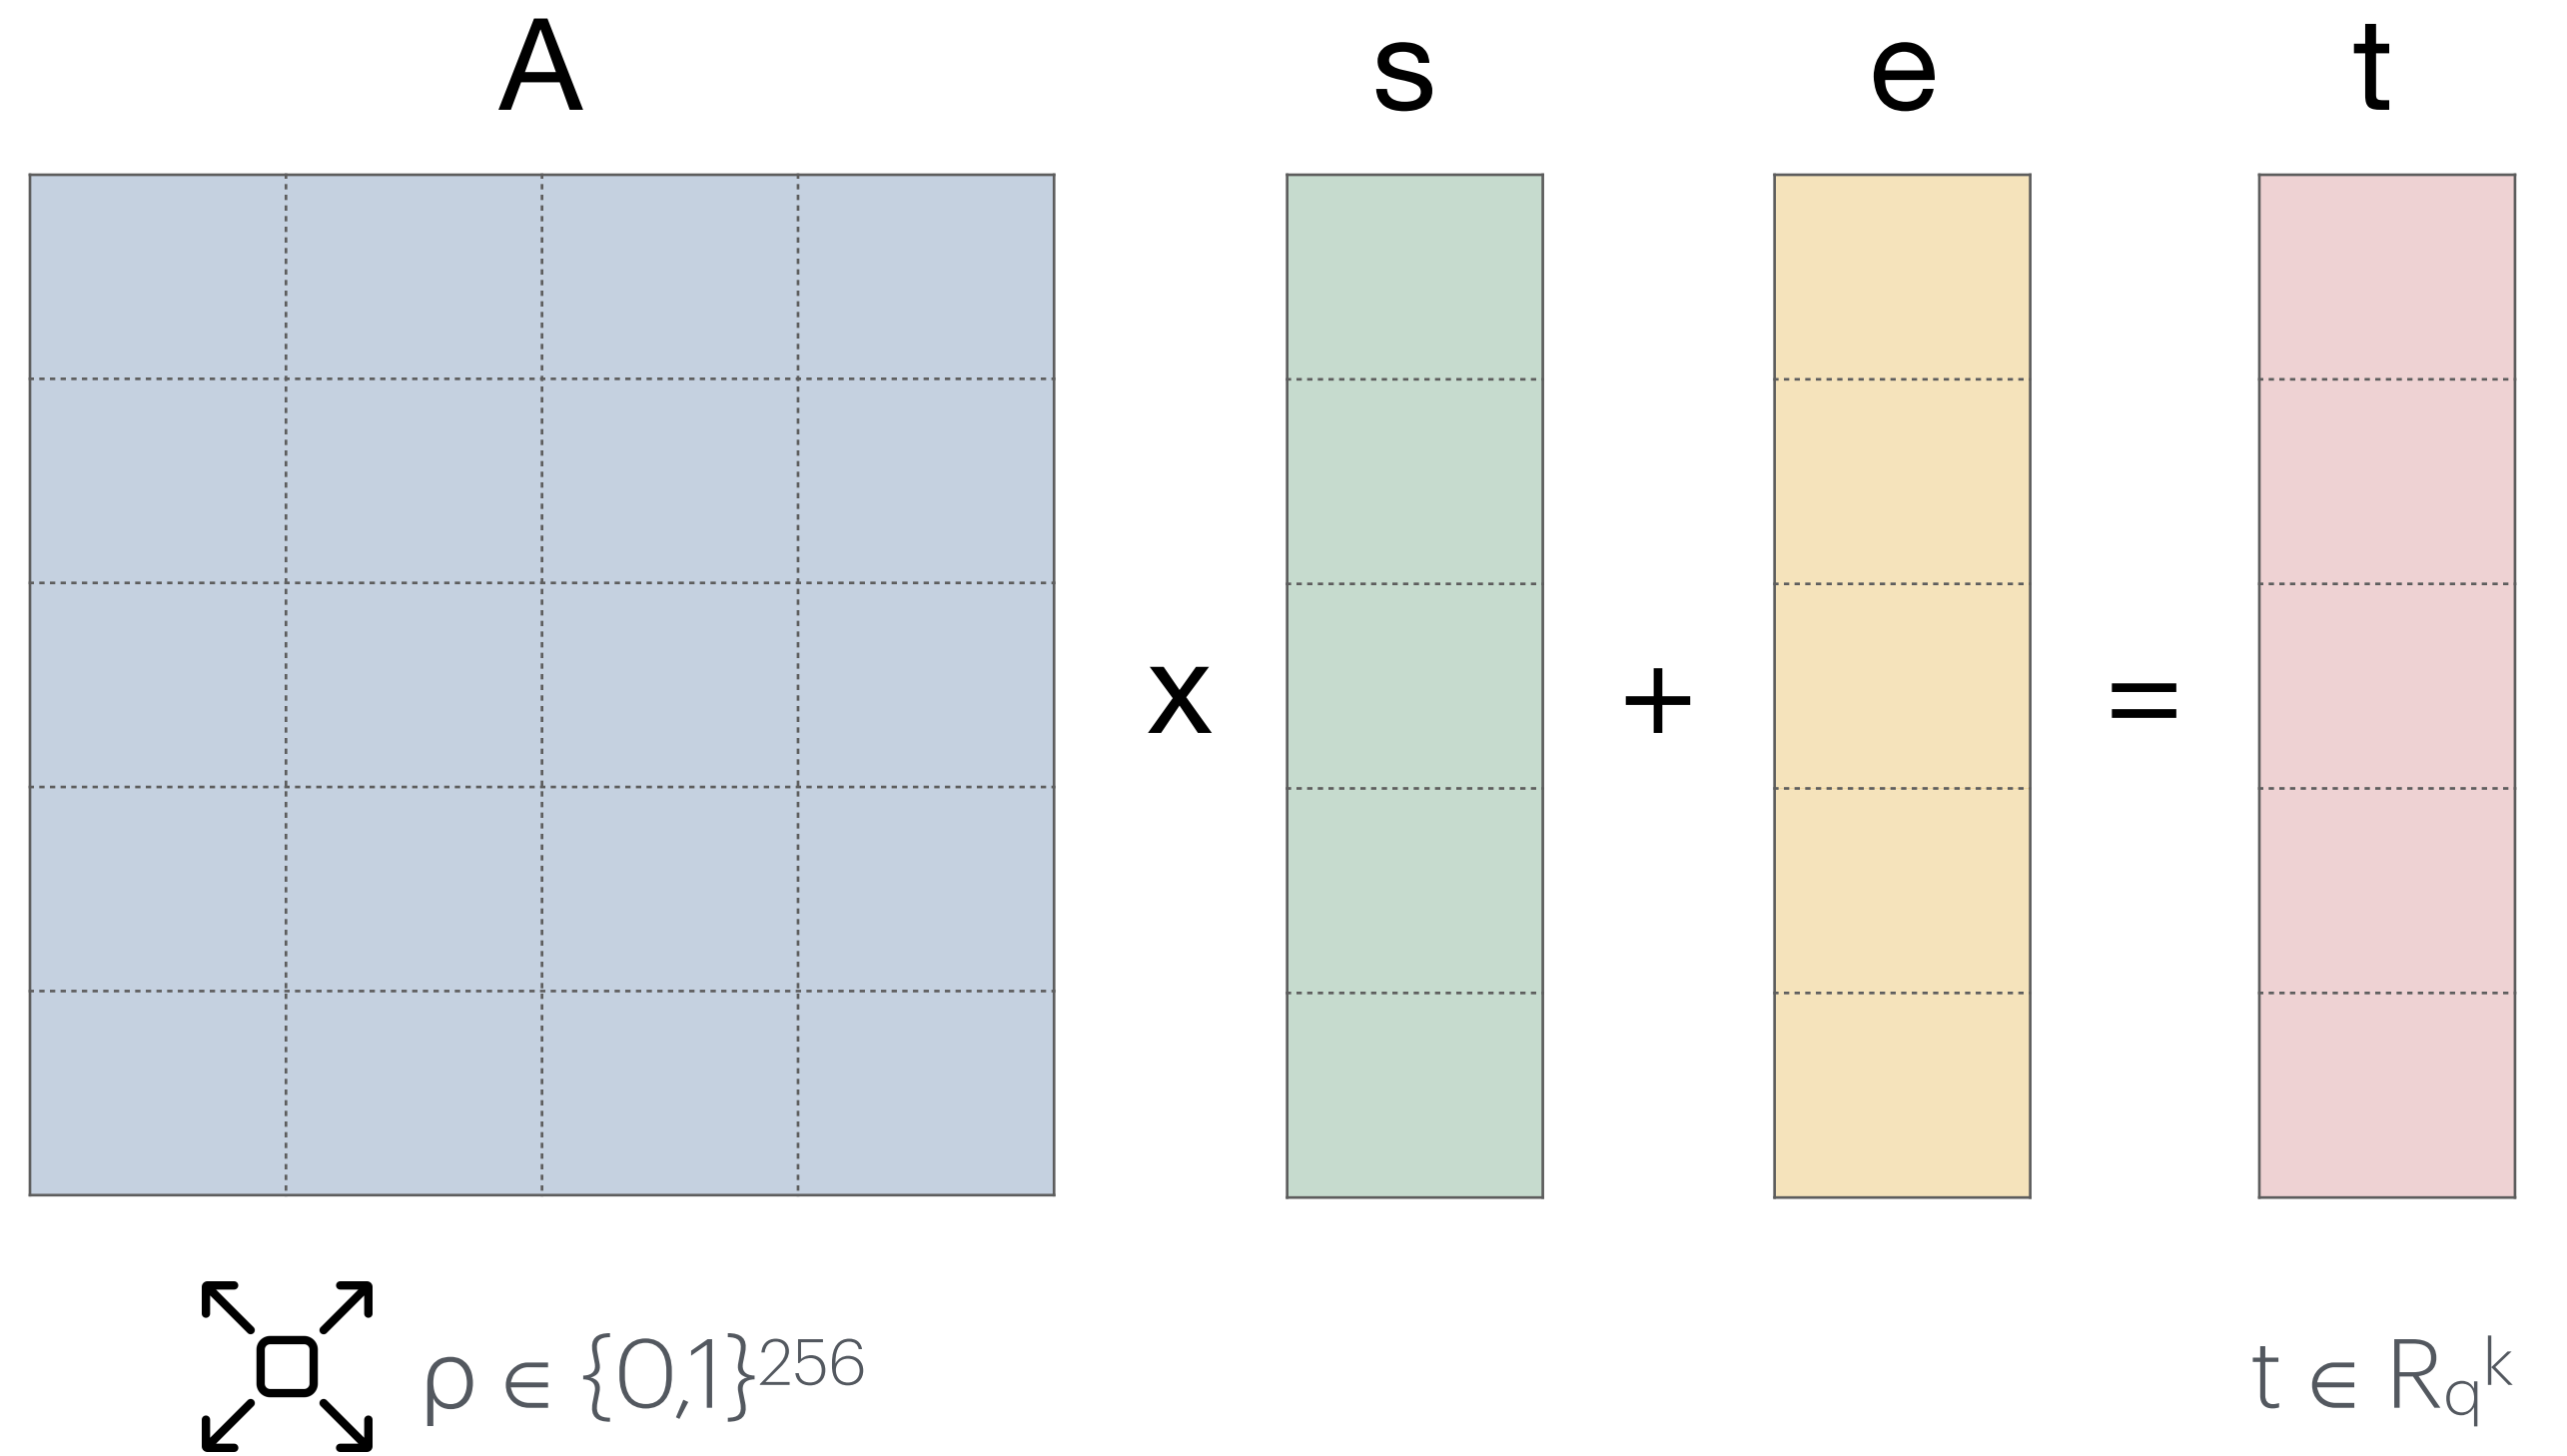

PAKEM [AHH+24]

Challenges in instantiating IC over groups

- Usually, ideal ciphers are instantiated with block ciphers.
- But what if we have an IC over a group?
- The domain of the IC and its instantiation must coincide; otherwise, it becomes trivial for an adversary to mount an offline dictionary attack. The attack proceeds as follows:
 1. Intercept $apk = IC.Enc(pw, pk)$.
 2. Decrypt apk using a candidate password pw^* .
 3. If $pk^* = IC.Dec(pw^*, apk)$ does not belong to the public key space, then pw^* is incorrect.

ML-KEM public keys

- Sample $\rho \in \{0,1\}^{256}$
- $A \leftarrow \text{Expand}(\rho) \in R_q^{k \times k}$
- $t \leftarrow A * s + e$
- $\text{pk} \leftarrow (\rho, t)$

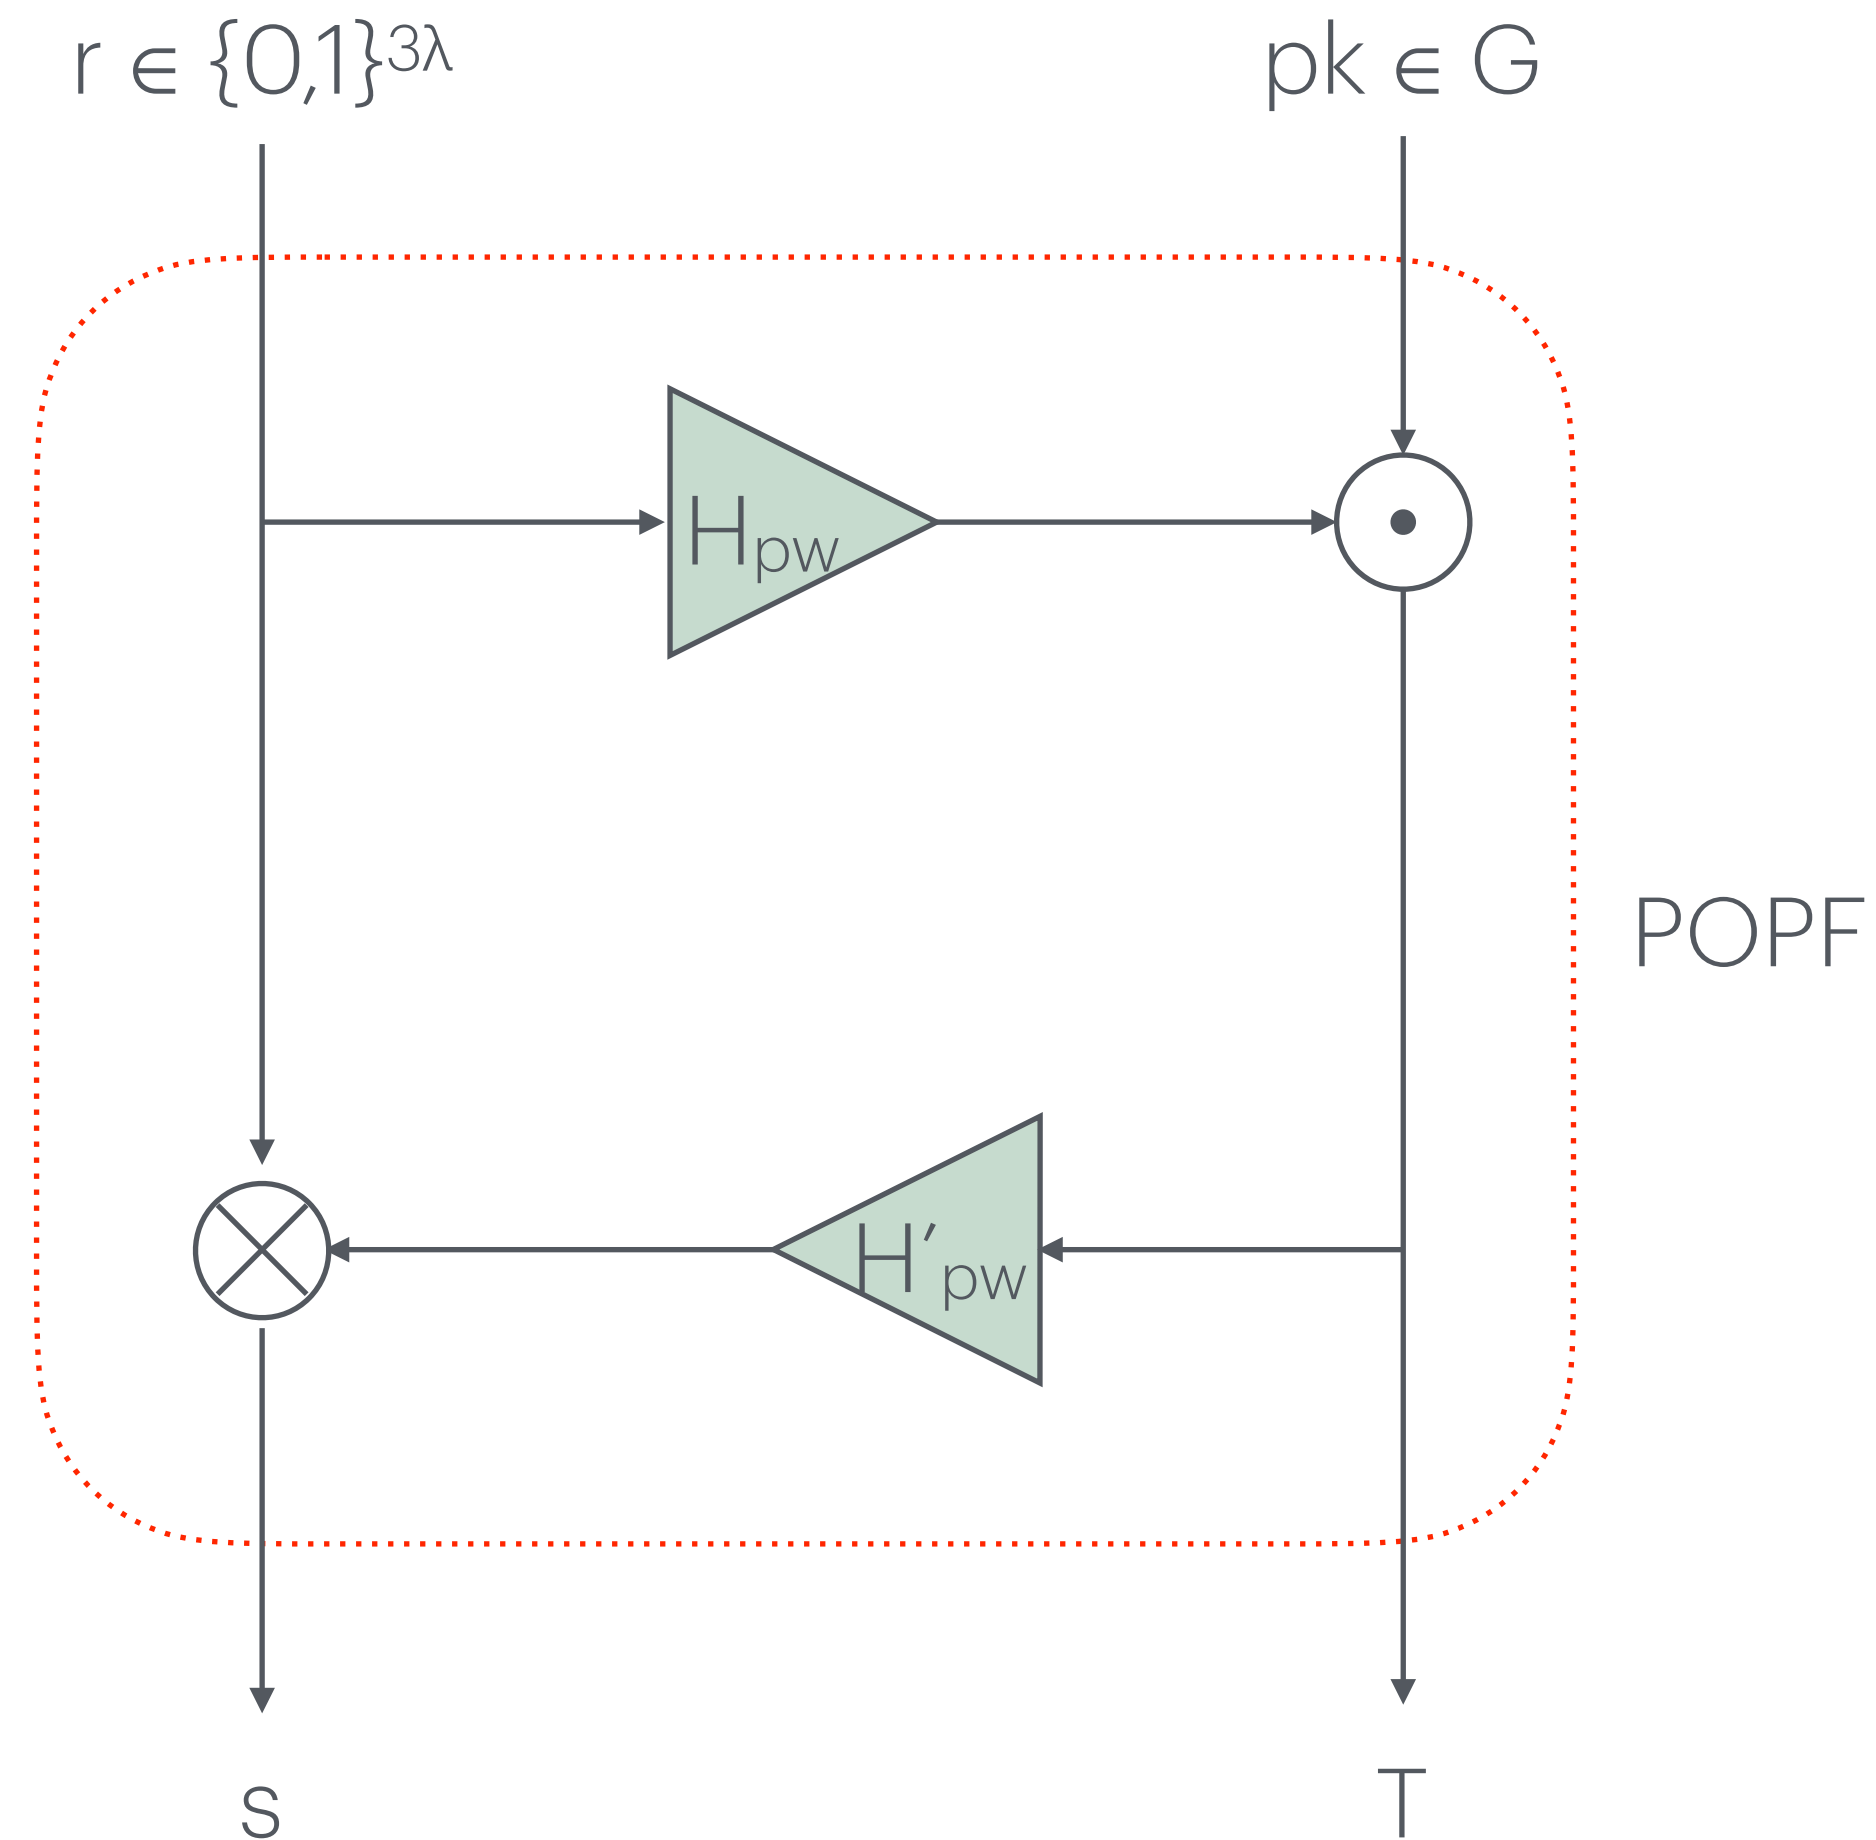

ML-KEM public keys

- R_q is a ring where the elements are polynomials with coefficients in Z_q
- FIPS 203 specifications set $q = 3329$
- $2^{11} < 3329 < 2^{12}$
- To encode a single element in Z_{3329} , we need 12 bits

2-round Feistel [MRR20]

- Password-encrypt with a 2-round Feistel (2F).
- Public key on the right wire; random coins on the left wire.
- Ciphertext expands pk .
- Only one hash onto group needed instead of IC over the group.
- Modular approach with game-based definition POPF. However, 2F permits some malleability and POPF is insufficient for (O)EKE constructions.

A modified 2-round Feistel [SGJ23]

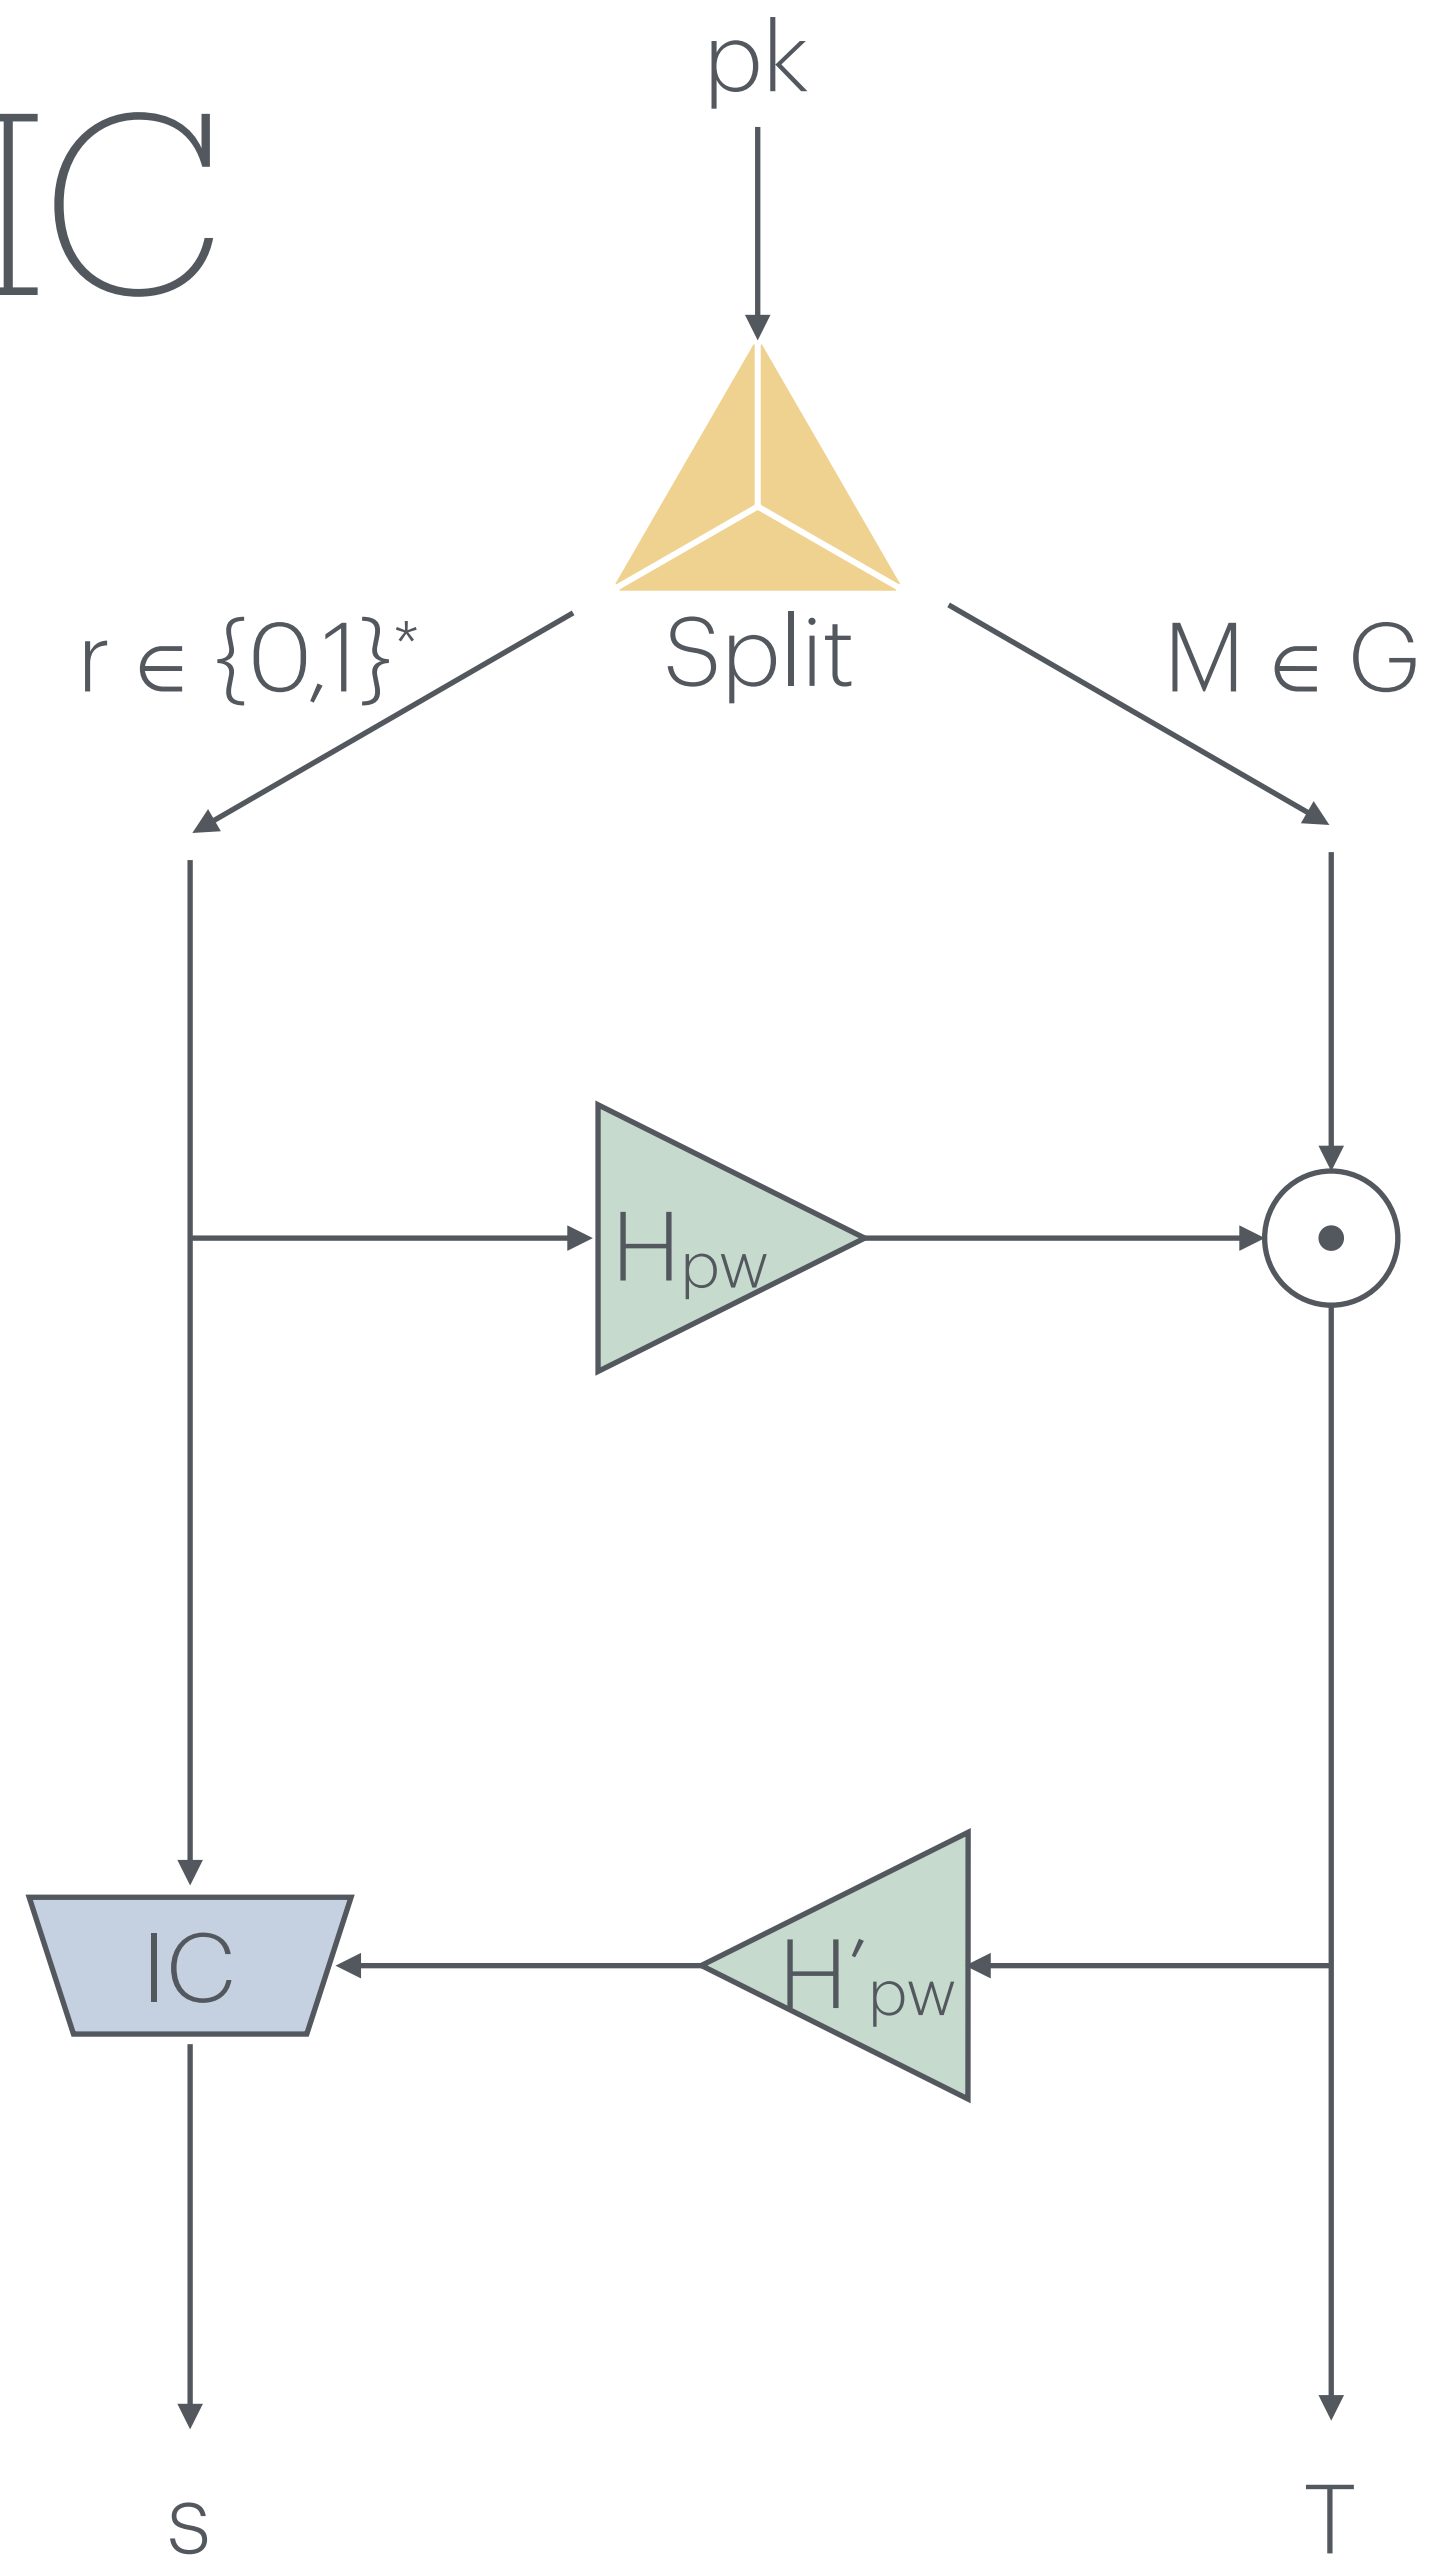

- Replace XOR operation with IC to avoid malleability

easy to instantiate

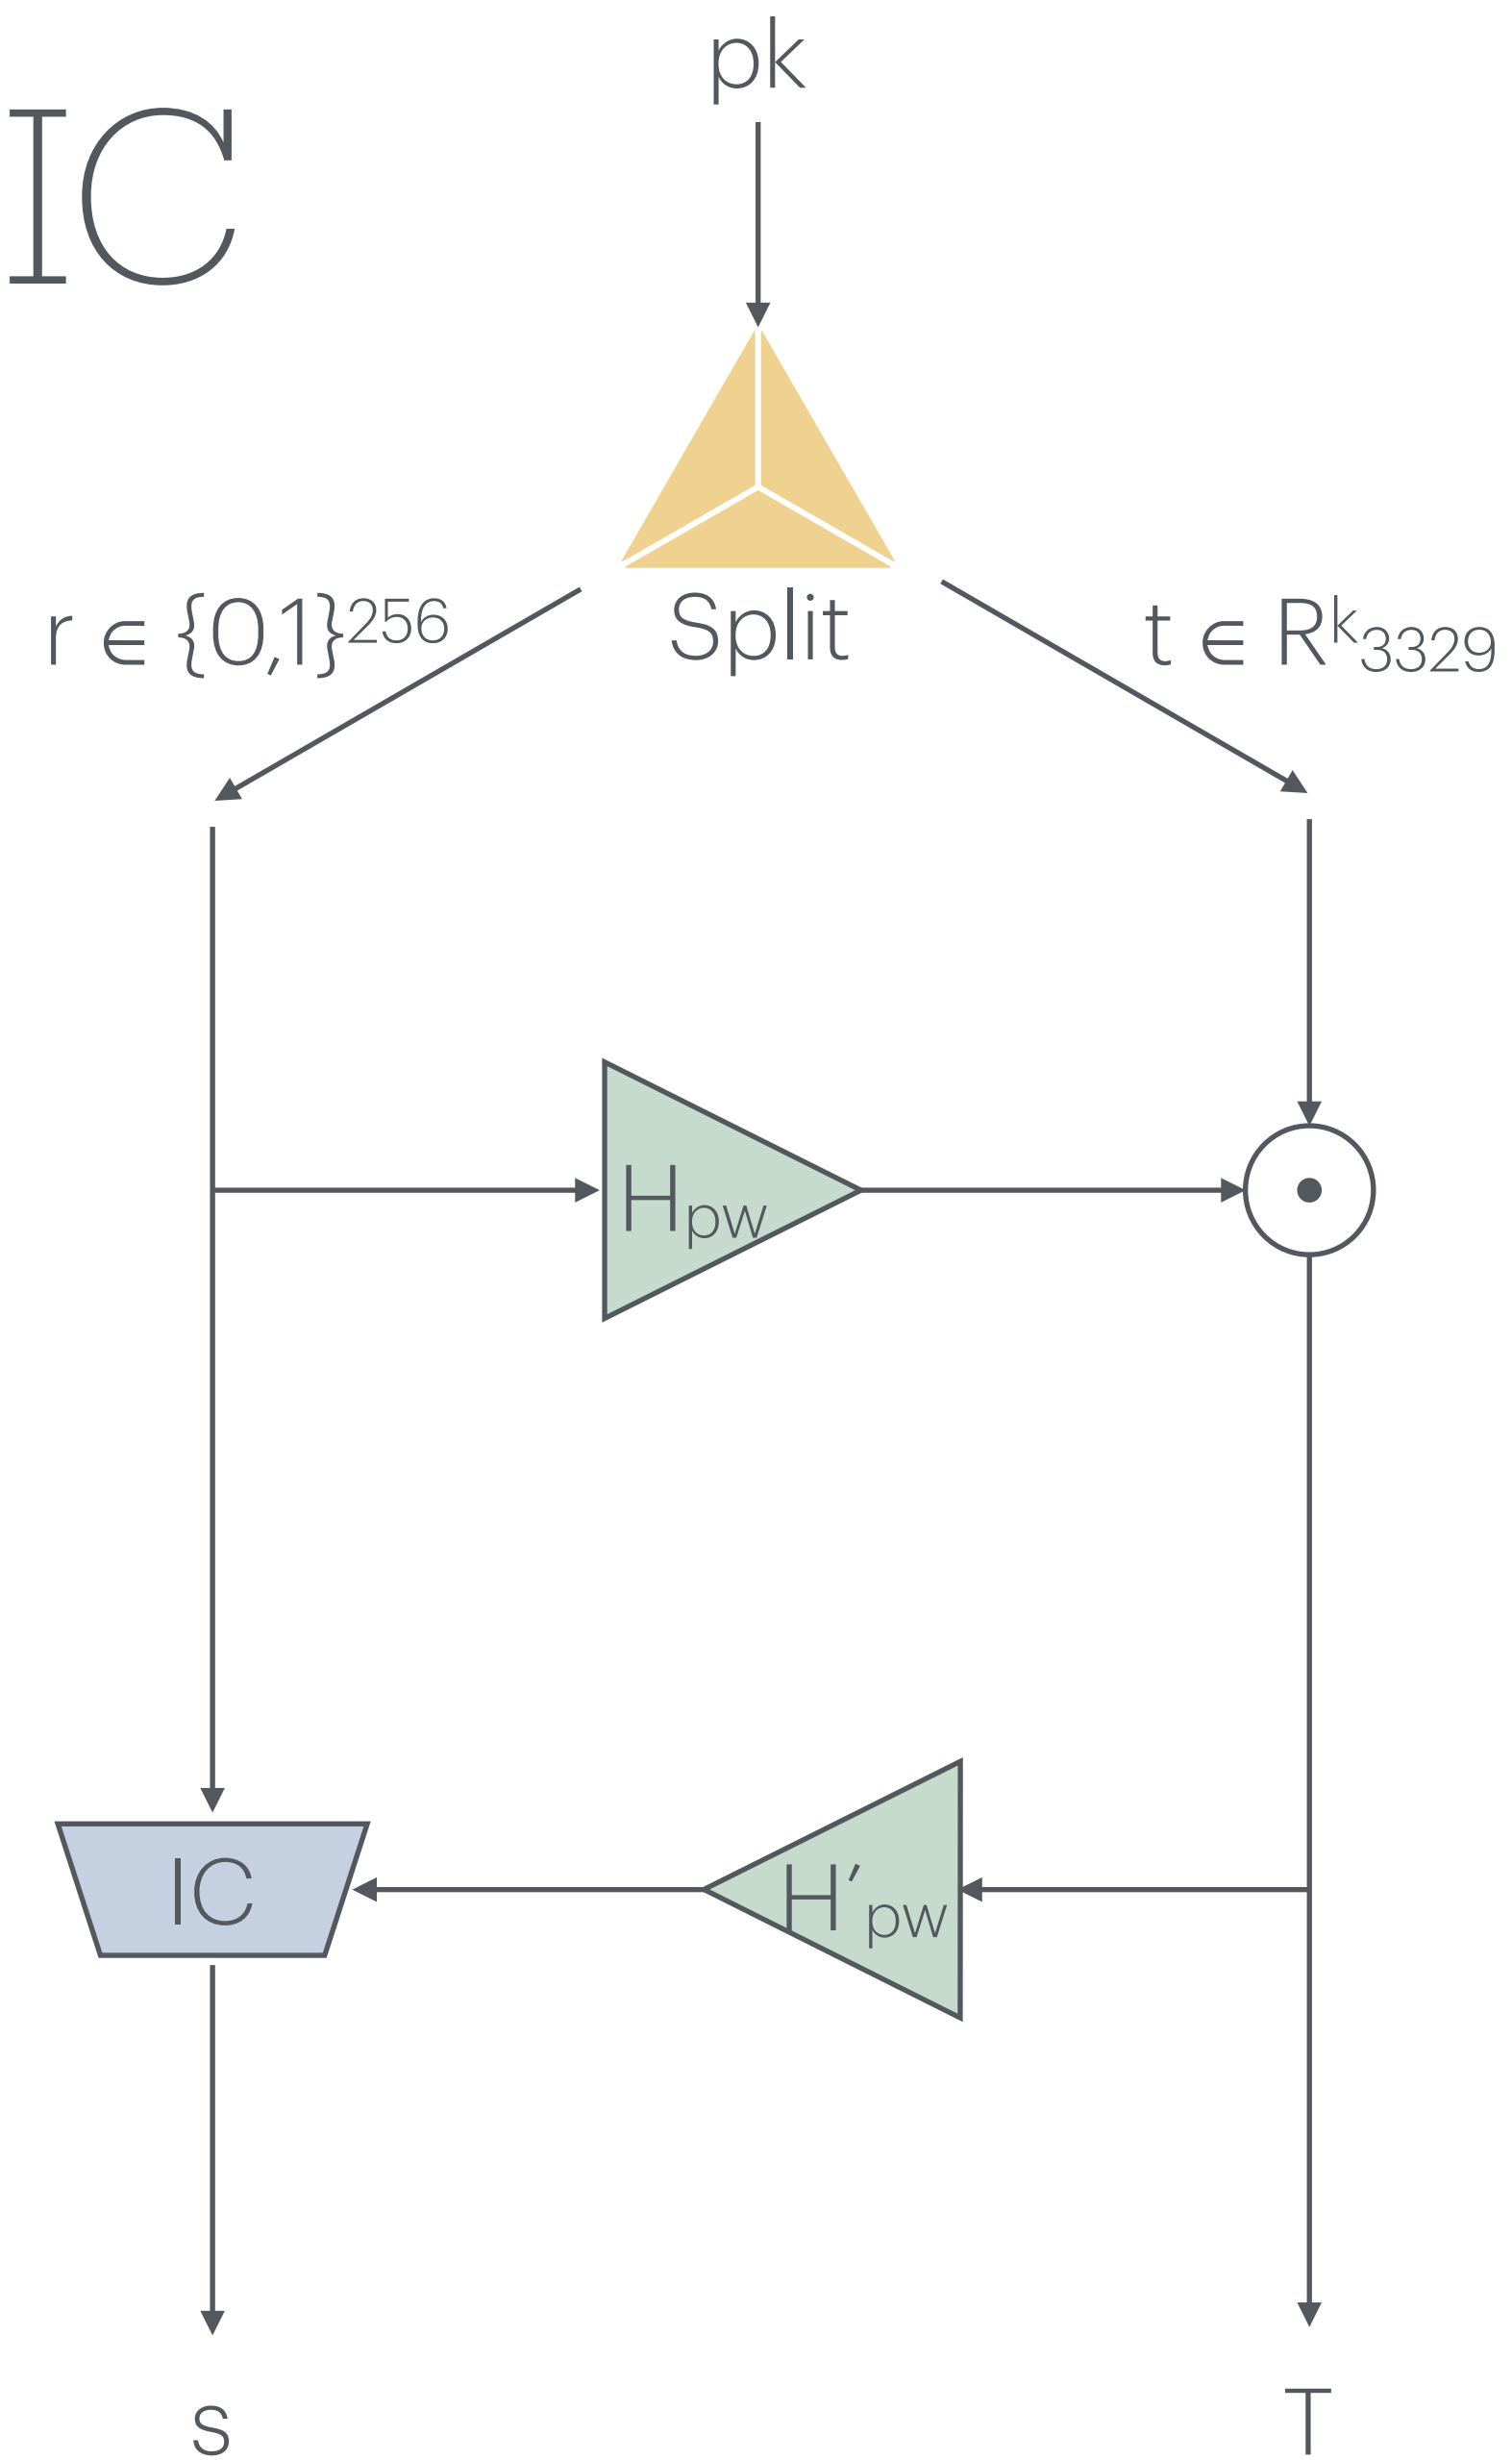

- IC over bit strings
- Modular approach with UC definition: Half-Ideal Cipher (HIC)
- Why “half-ideal”? The s -part is random.

Compact HIC

- Can we split the public and feed both wires of the $2F$?

Compact HIC

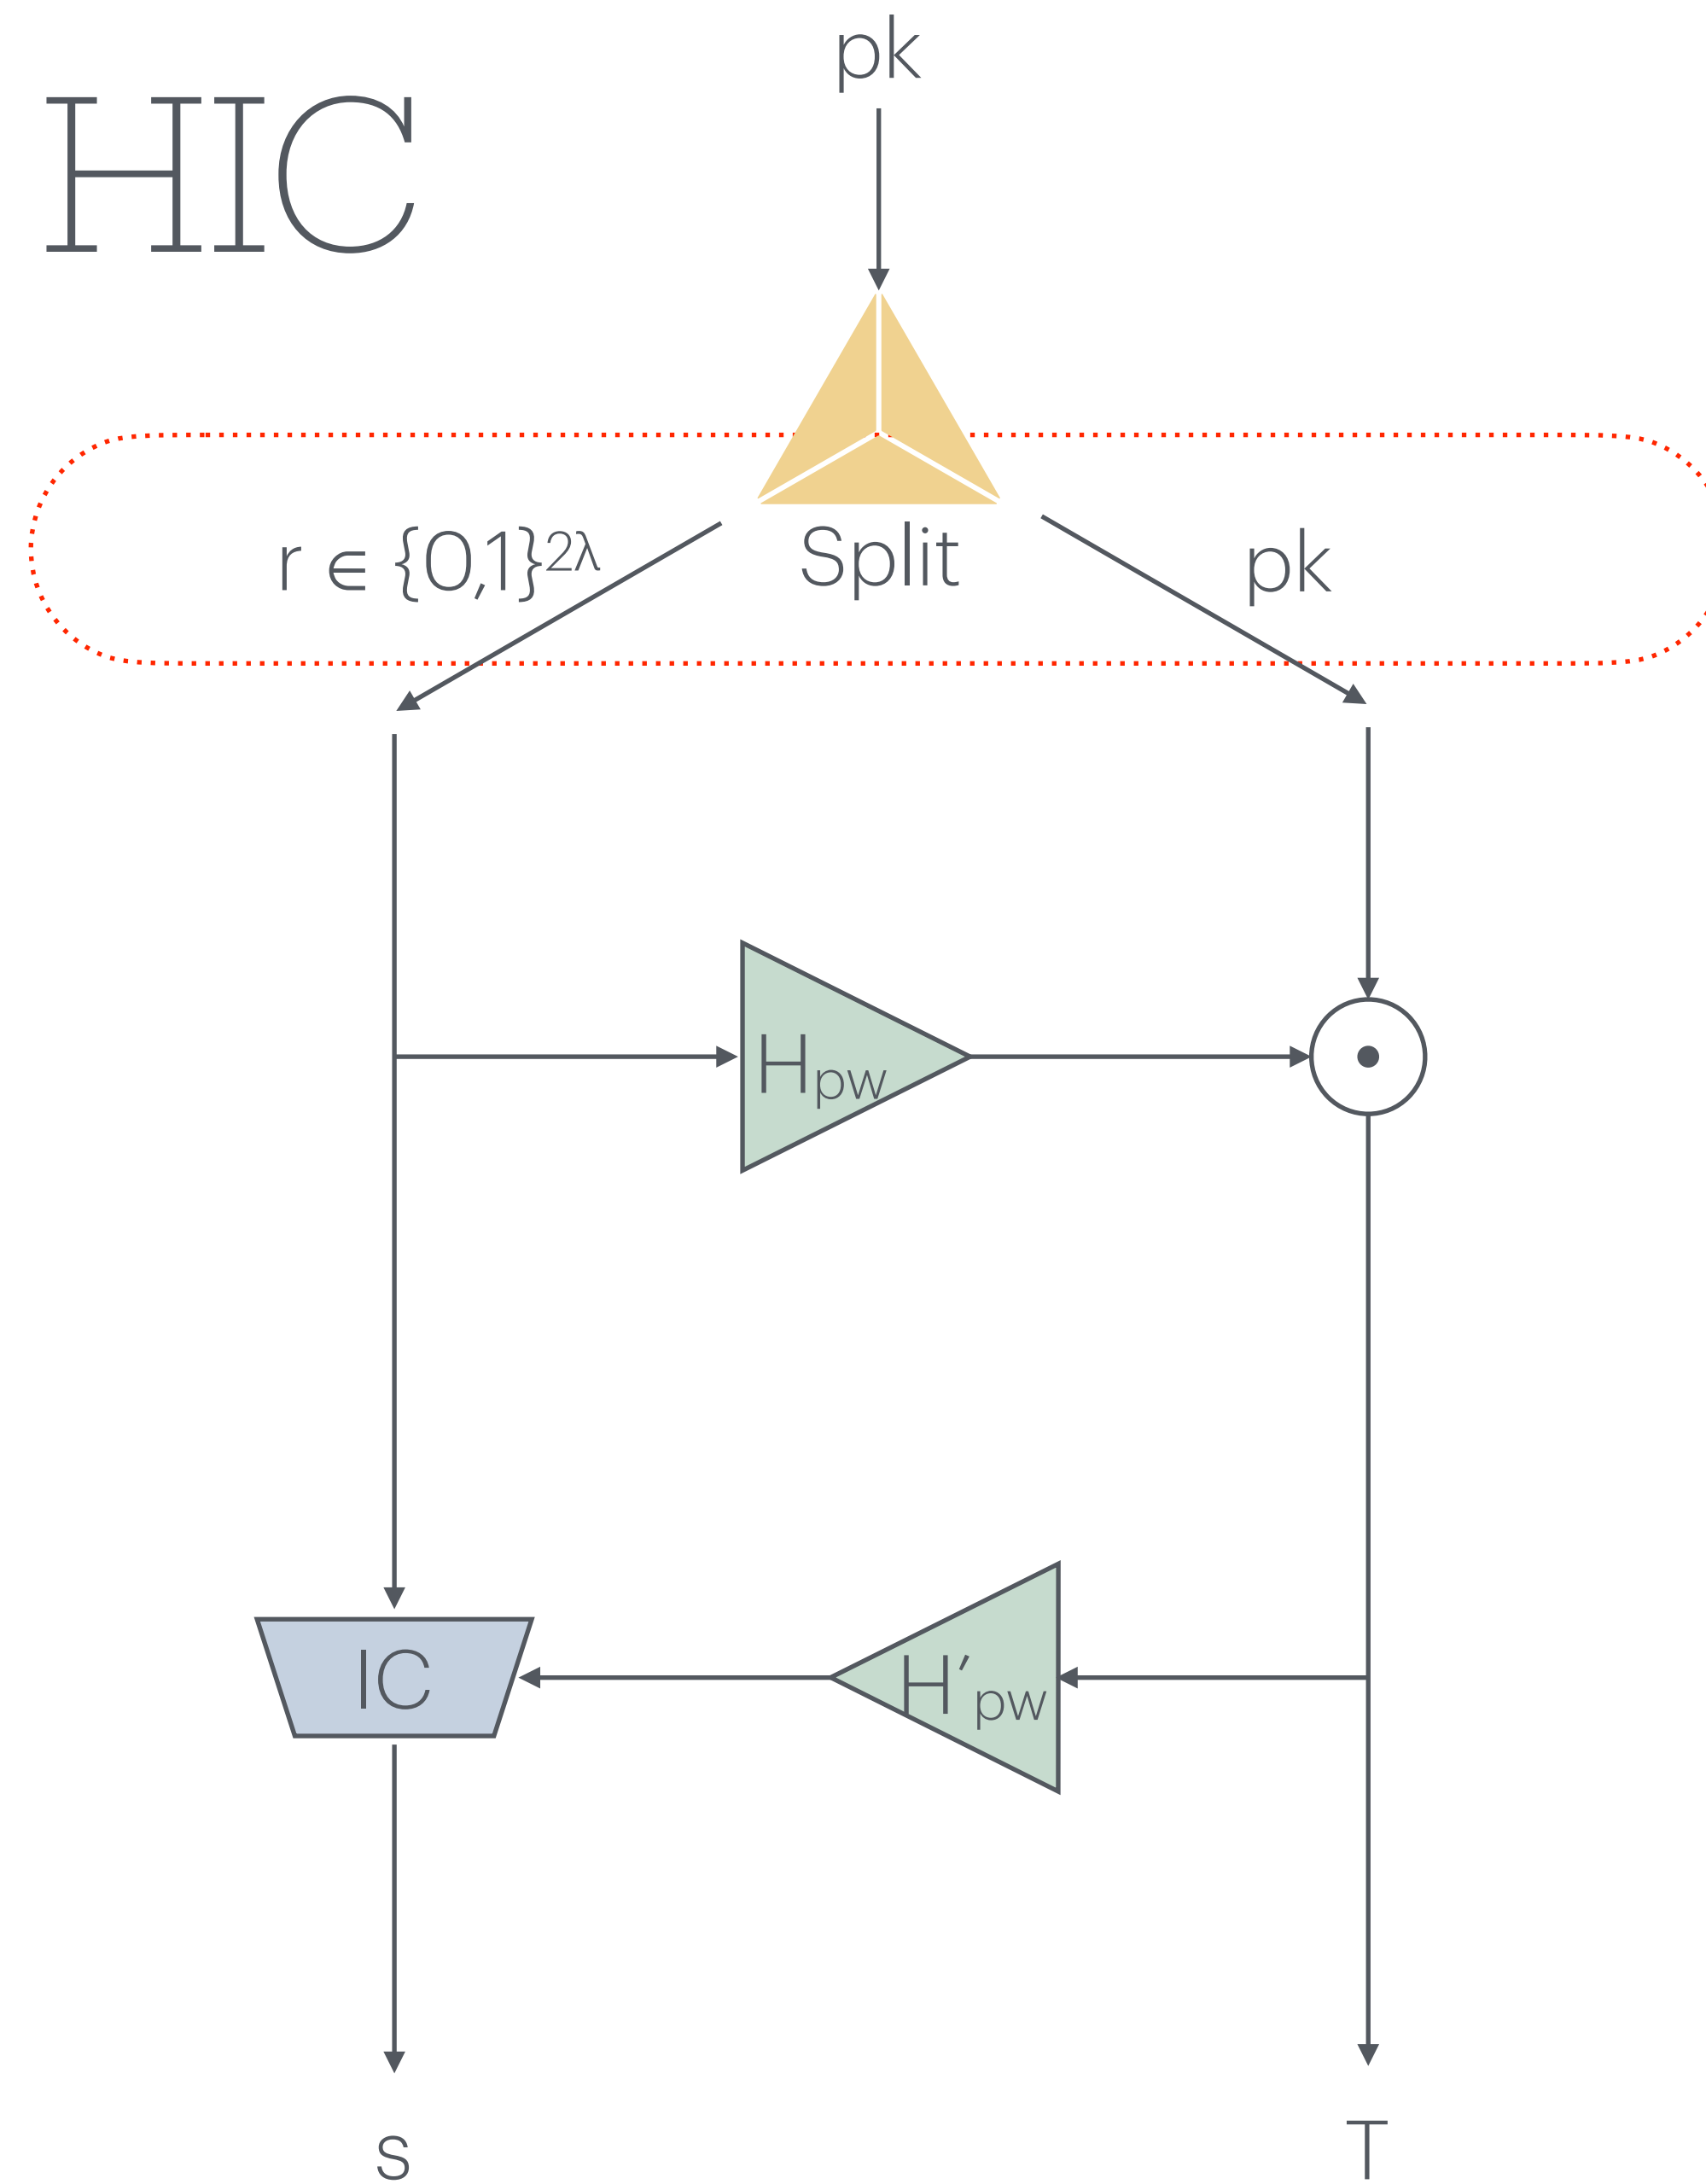

- In particular, we are interested in the trivial breakdown of ML-KEM public keys.
- Compact: avoids ciphertext expansion!
- Effectively, de-randomizes HIC.

Compact HIC

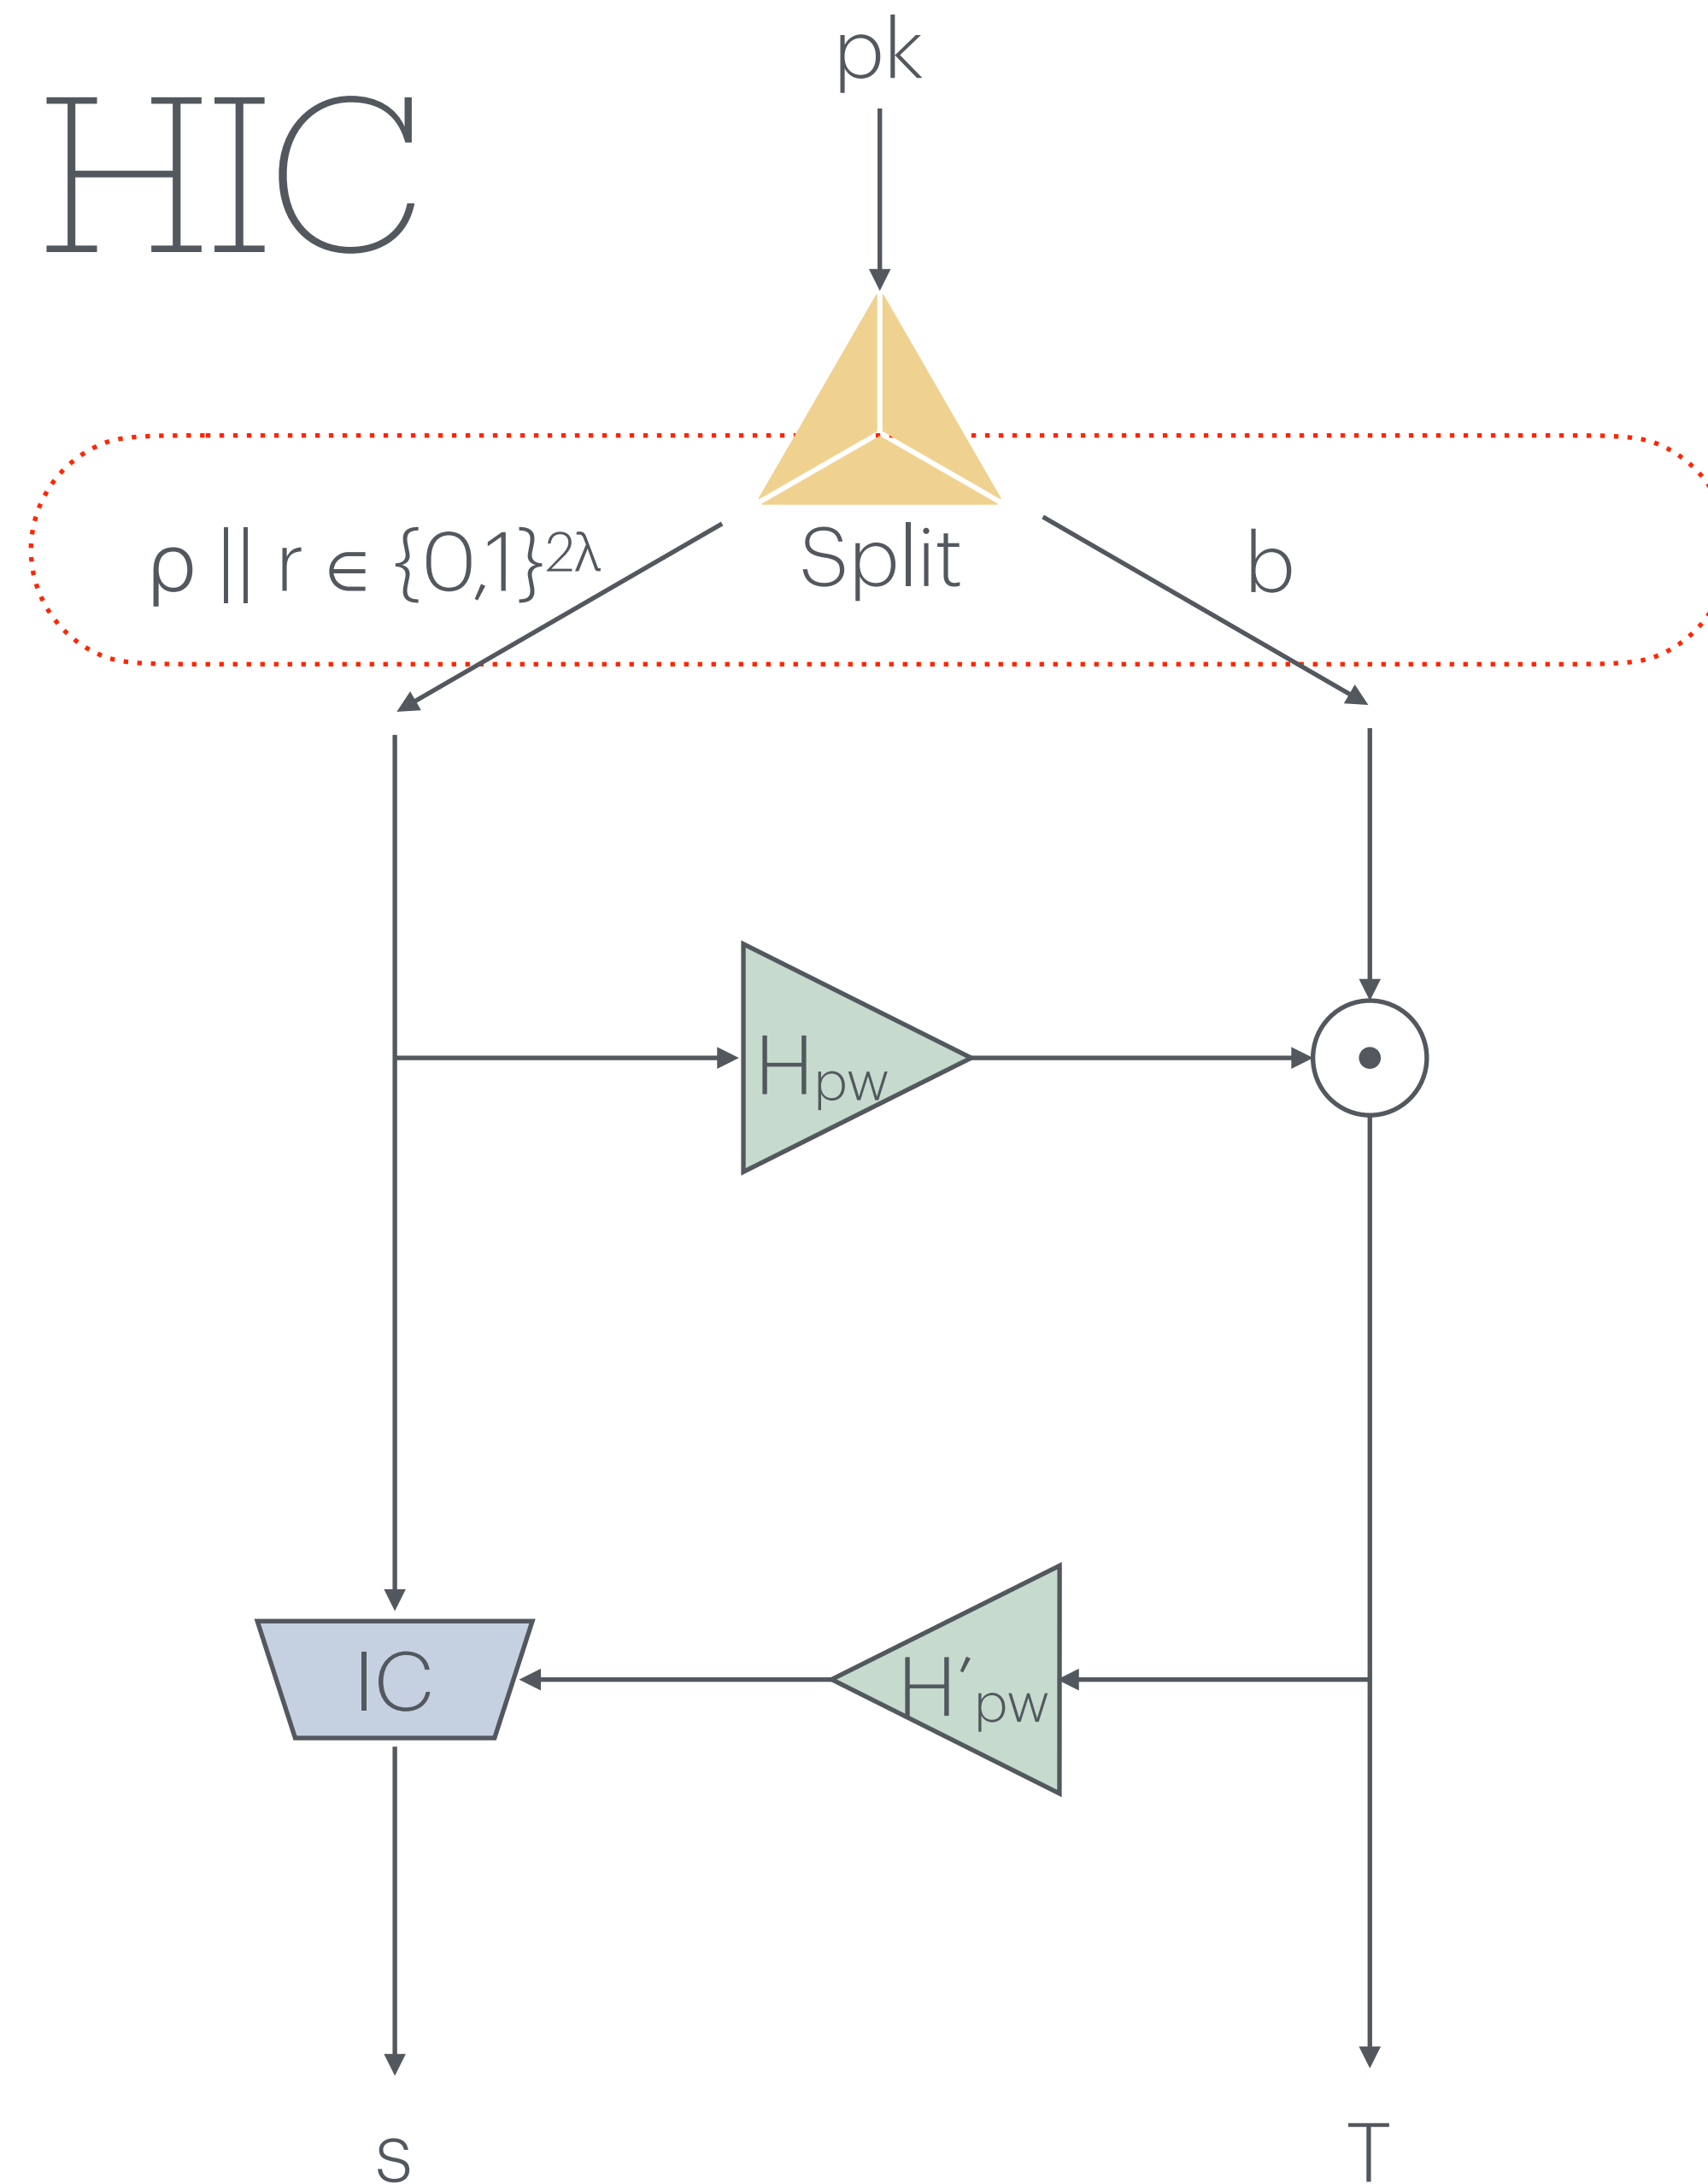

- In general, (O)EKE constructions require public keys to be uniformly distributed.
- HIC requires uniform r .
- We can combine both requirements into a single definition w.r.t. function **Split**.
- Experiment UNI-PK:
 $(_, pk_0) \leftarrow \text{Keygen}$
 $(r_0, M_0) \leftarrow \text{Split}(pk_0)$
 $(r_1, M_1) \leftarrow \{0,1\}^{2\lambda} \times G_\lambda$
 $b \leftarrow \{0,1\}$
 $b' \leftarrow A(r_b, M_b)$
return $b == b'$

Compact HIC

- The randomized identity **Split** recovers standard public key uniformity (also known as *fuzziness* [BCP+23]).
- Leads back to the HIC construction [SGJ23].

Compact HIC

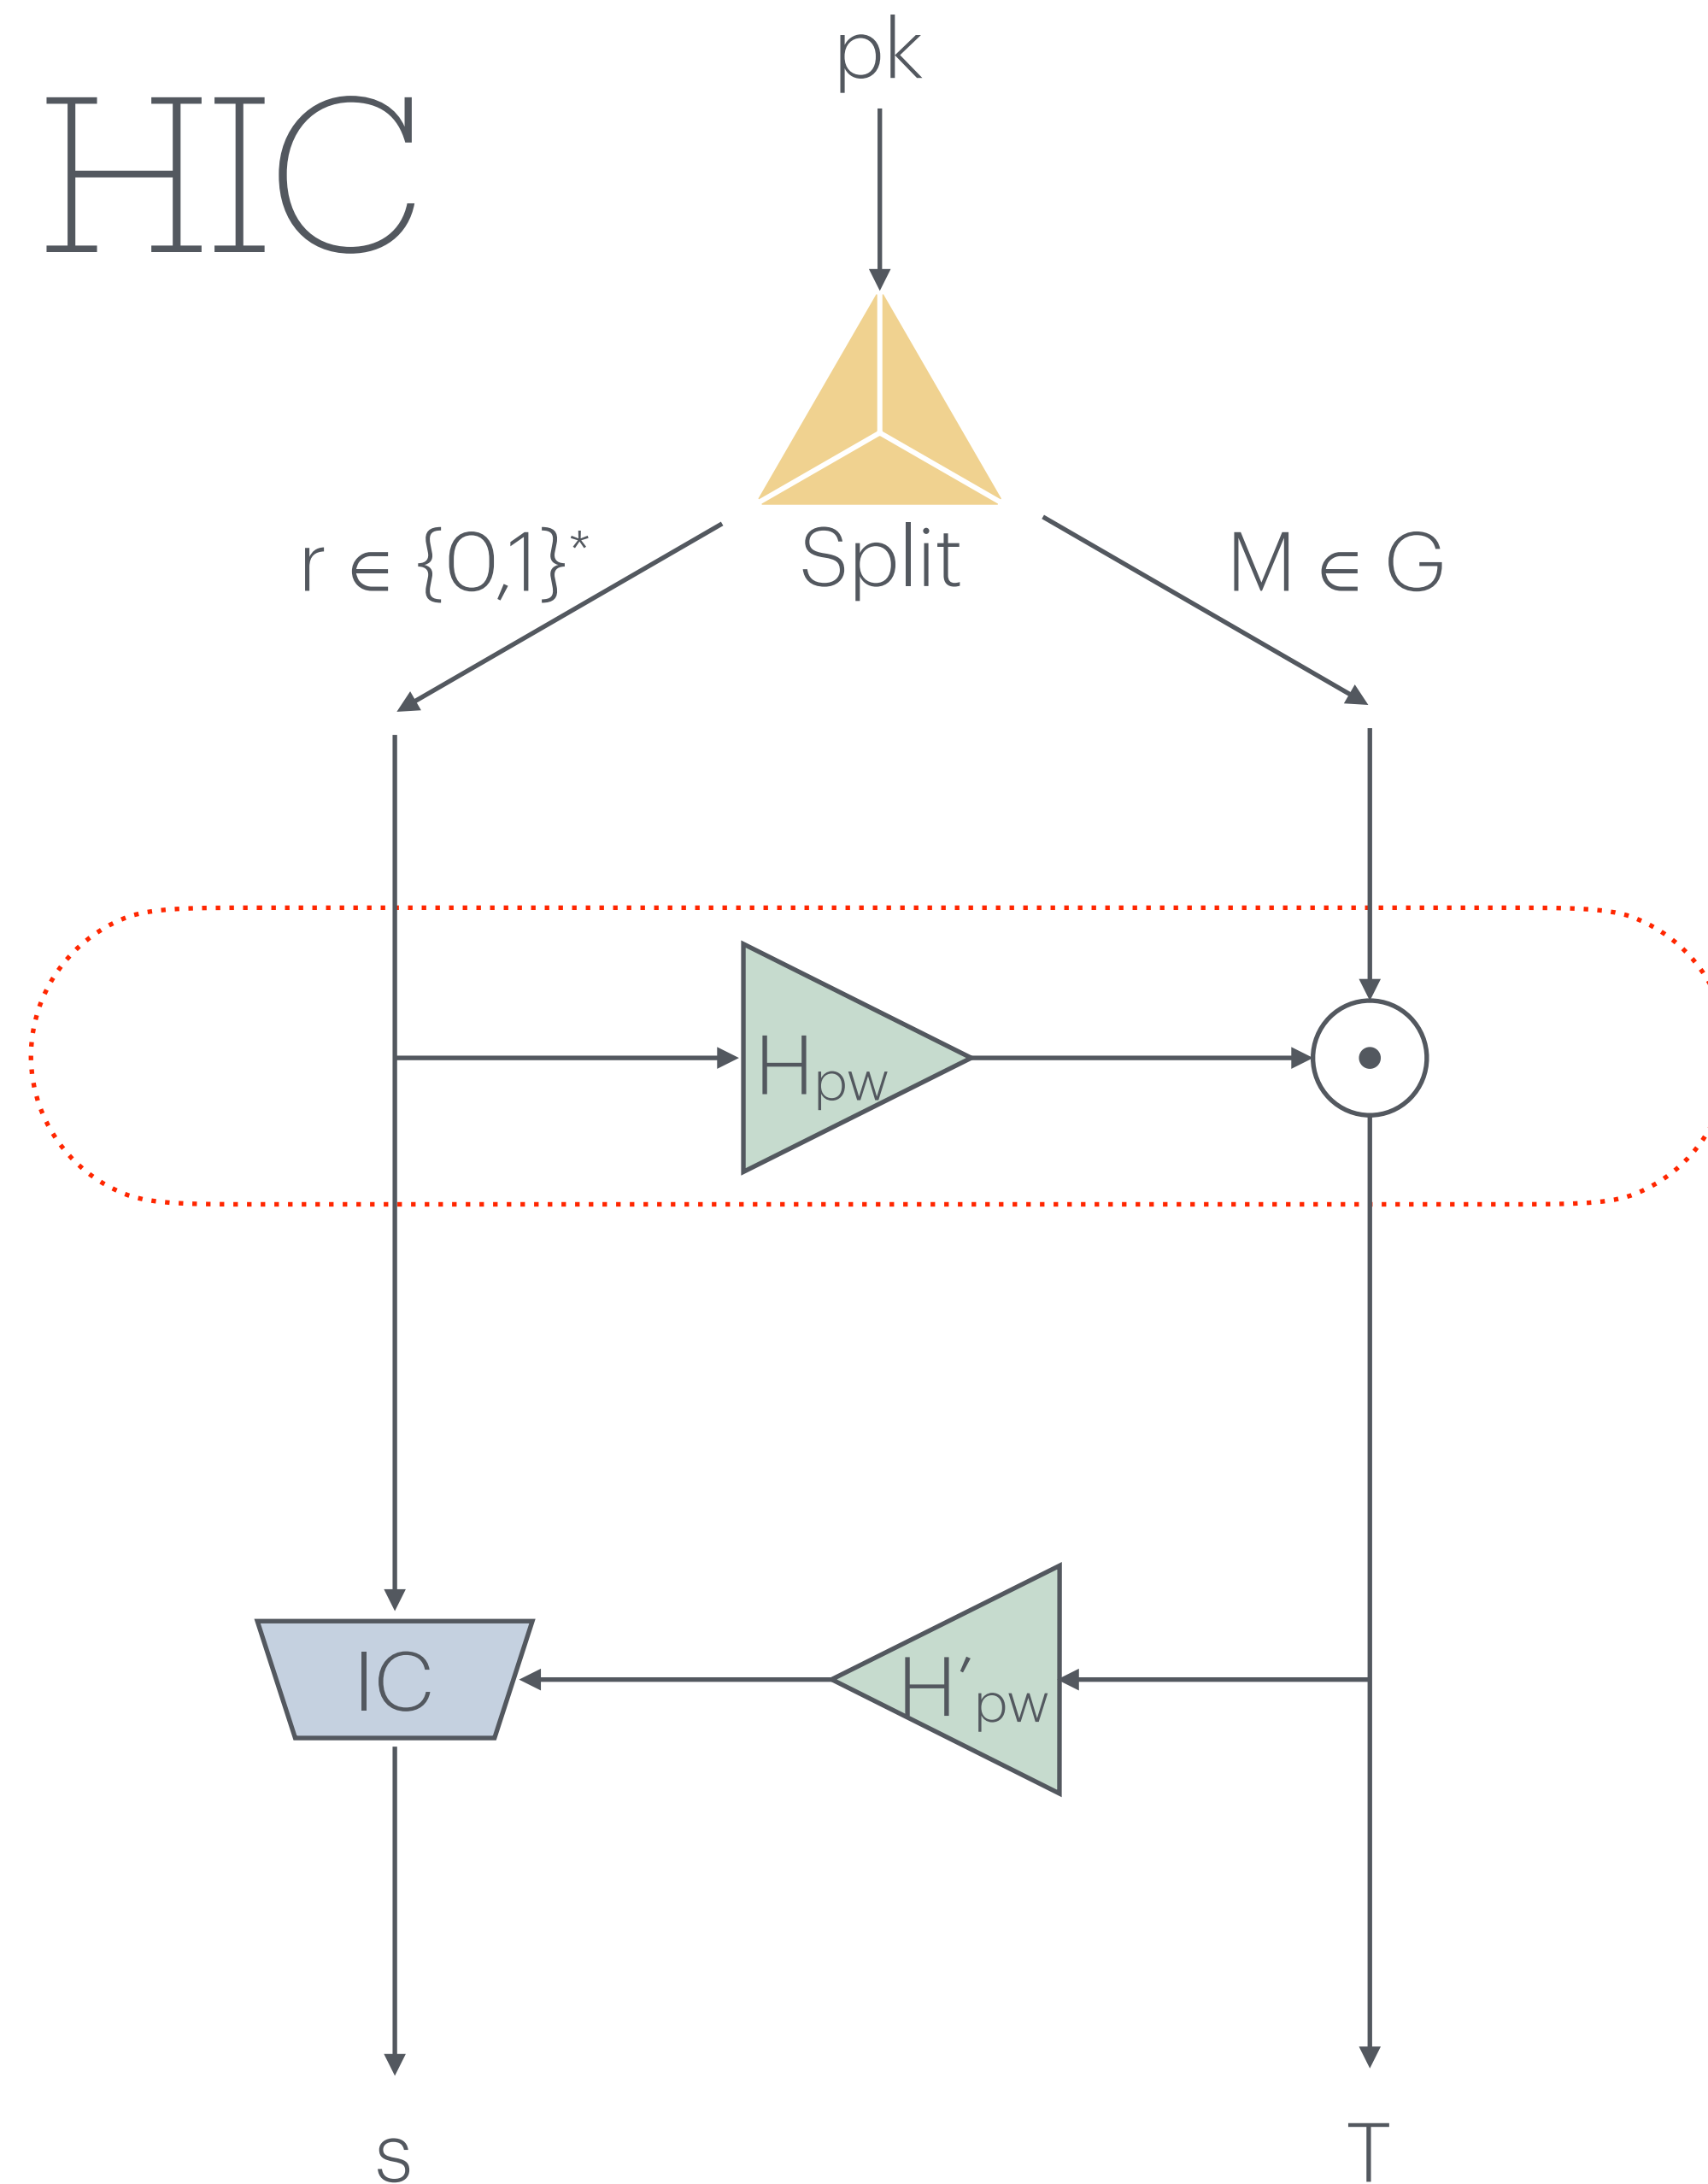

- FrodoKEM determines seed $\rho \in \{0,1\}^{128}$.
- A Randomized Split can easily extend FrodoKEM keys by appending random bits to ρ , ensuring it reaches the required length.
- This approach requires no modifications to FrodoKEM.

Compact HIC

- F_{HIC} features honest interfaces accessible by the environment Z , but no control over randomness r is provided.
- Unfortunately, we lose the modular HIC abstraction.
- Solution: Direct proof.

Compact HIC

- How to instantiate hash-onto-group H ?
 - ★ FrodoKEM makes it easy because it uses power-of-two modulus. Simply use an eXtendable Output Function (XOF).
 - ★ For ML-KEM we reuse the rejection sampling procedure used to expand p into a matrix A of polynomial coefficient modulus 3329.

The CHIC protocol

Requirements from KEM

CHIC UC-realizes F_{PAKE} [CHK05] in the RO and IC model provided that KEM has the following properties:

- **One-wayness of ciphertexts:** OW-CPA, but OW-PCA leads to tighter reduction.
- **Anonymity of ciphertexts:** ANO-PCA. Actively-secure KEM is necessary.
- **Uniformity of public keys:** UNI-PK.

Benchmarks

Experimental results in microseconds. Comparison of execution times of CHIC participants (two initiator stages and responder single stage) with respect to key exchange using only a CPA or CCA Kyber KEM.

| | CPA KEM | | | CCA KEM | | | CHIC | | |
|-----------|---------|-----|-----|---------|-----|-----|-------|------|-----|
| | Keygen | Enc | Dec | Keygen | Enc | Dec | Start | Resp | End |
| Kyber512 | 25 | 29 | 9 | 45 | 49 | 12 | 70 | 74 | 14 |
| Kyber768 | 28 | 36 | 41 | 49 | 59 | 65 | 75 | 85 | 93 |
| Kyber1024 | 36 | 56 | 53 | 61 | 87 | 83 | 89 | 123 | 117 |

Final remarks / future work

On timing-attacks 

- The rejection-sampling of ML-KEM is not constant-time, meaning Keygen is not constant-time.
- Timing attacks potentially affect any ML-KEM to PAKE compiler, regardless of how we instantiate the hash onto group H .
- FIPS 203 allows to limit the number of iterations of SampleNTT to 280, with a probability of failure of 2^{-261} .
- We are exploring how to implement a constant-time Keygen algorithm for ML-KEM and use it to instantiate the hash-to-group operation.

Final remarks / future work

On IC-256-256 

- AES has only been standardized only with a 128-bit block size. However, our proofs requires avoiding collisions across different block cipher keys. Therefore, we need to instantiate the IC with a block cipher with 256-bit size blocks and 256-bit length keys.
- To meet this requirement, we used Rijndael-256-256. If AES must be used, domain extenders can provide a solution [CDMS10].
- NIST is currently considering standardizing Rijndael-256-256 [edu.lu/pdmd3].

NIST

Final remarks / future work

On quantum adversaries

- The current proof is in the RO and IC model.
- However, a *harvest-now-decrypt-later* attack is ineffective against CHIC because the ciphertexts are post-quantum secure.

Thank you for your attention
