explorations

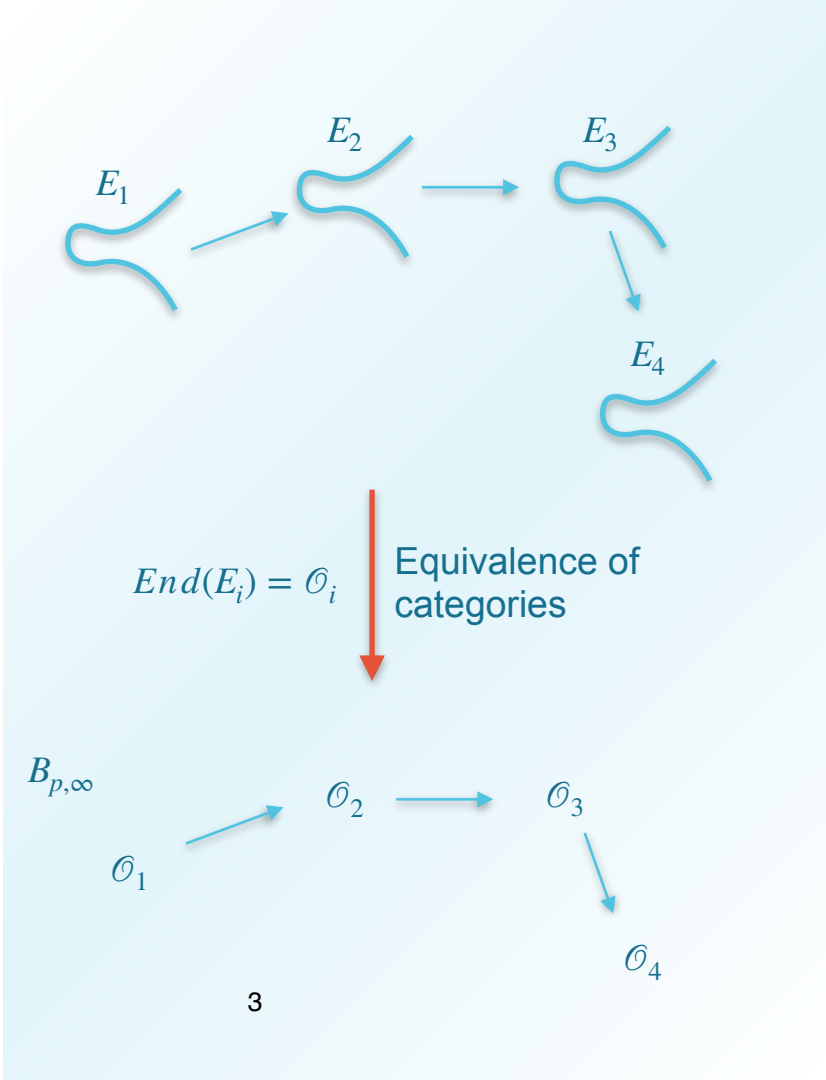

# Isogeny-based cryptography

- A promising candidate for post-quantum cryptography.
- The *pure isogeny problem*—finding an explicit isogeny between two elliptic curves.
- Most isogeny-based protocols rely on the pure isogeny problem or on some variants of this problem.

# Deuring correspondence

There is a bijection between conjugacy classes of supersingular  $j$ -invariants and maximal orders (up to isomorphisms) of the quaternion algebra.

# Deuring correspondence

Let  $E$  be a supersingular elliptic curve  
over finite field of characteristic  $p$ .

$End(E)$  is a maximal order  $\mathcal{O}$  in the  
quaternion algebra  $B_{p,\infty}$ .

# Deuring correspondence

An equivalence of categories of isogenies between supersingular elliptic curves over  $\overline{\mathbb{F}}_p$  and the left ideals of maximal orders of  $B_{p,\infty}$ .

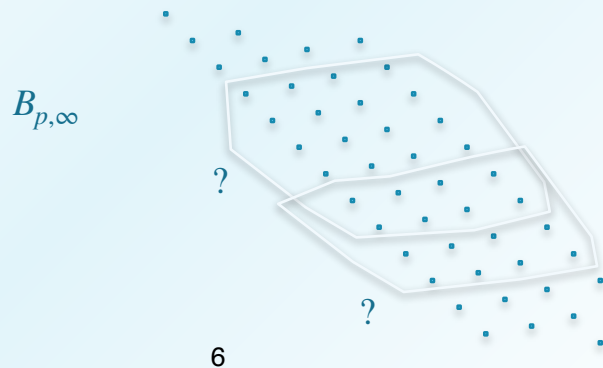

$$\text{End}(E_1) = \mathcal{O}_1$$

$$\text{End}(E_2) = \mathcal{O}_2$$

# Hard problems

- Computing the endomorphism ring of a supersingular elliptic curve.
- Computing any isogeny between two supersingular elliptic curves.
- Computing a degree  $d$  isogeny between two supersingular elliptic curves if it exists.

# Implications of improved computation of degree-d isogeny

## Security of some schemes

*Exploring SIDH-based signature parameters* by Basso, Chen, Fouotsa, Kutas, Laval, Marco, Saah is based on on the hardness of finding fixed-degree isogenies.

## Performance

Speed-up of SQIsign: not being able to compute an isogeny of optimal length slows down the protocol significantly.

# Fixed degree isogeny

Let  $\epsilon > 0$  such that  $d \approx p^{\frac{1}{2} + \epsilon}$ . Up to what value of  $\epsilon$  can we compute an isogeny of degree  $d$ ?

(there exist strategies to compute an isogeny of degree  $< p^{\frac{1}{2}}$  and  $> p^3$ )

$$\text{End}(E_1) = \mathcal{O}_1$$

$$\text{End}(E_2) = \mathcal{O}_2$$

# State-of-the-art for fixed degree isogeny

- Exhaustive search over all outgoing isogenies: cost  $O(d)$ .
- Meet-in-the-middle: cost  $O^*(\sqrt{d})$  time and memory (smooth  $d$ ).
- van Oorschot-Wiener collision search variants: cost depends heavily on available memory.

# State of the art (quantum)

- Grover's algorithm improves exhaustive search to  $O^*(\sqrt{d})$ .
- (Tani's algorithm:  $d^{\frac{1}{3}}$ )

# Our strategy

- Compute  $End(E_1) = \mathcal{O}_1, End(E_2) = \mathcal{O}_2$  (Eisenträger et al.).
- Compute connecting ideal  $I$  between  $\mathcal{O}_1$  and  $\mathcal{O}_2$  (Kirschmer-Voight).

$$End(E_1) = \mathcal{O}_1$$

$$End(E_2) = \mathcal{O}_2$$

# Our strategy

- Compute the norm form associated to  $I$  (reduced Gram matrix):

$$x^T \bar{I} x = Q(x_1, x_2, x_3, x_4).$$

- Represent  $d$  via this norm form:

$$Q(x_1, x_2, x_3, x_4) = \text{norm}(I) \cdot d.$$

- Compute an ideal  $J$  equivalent to  $I$ :

$$J = I \frac{\bar{x}}{\text{norm}(I)}.$$

$$\text{End}(E_1) = \mathcal{O}_1$$

$$\text{End}(E_2) = \mathcal{O}_2$$

$$Q(x_1, x_2, x_3, x_4) = \text{norm}(I) \cdot d$$

# Our strategy

- We have an ideal  $J$  of norm  $d$  and can convert it to the isogeny of degree  $d$ .

$$\text{End}(E_1) = \mathcal{O}_1$$

$$\text{End}(E_2) = \mathcal{O}_2$$

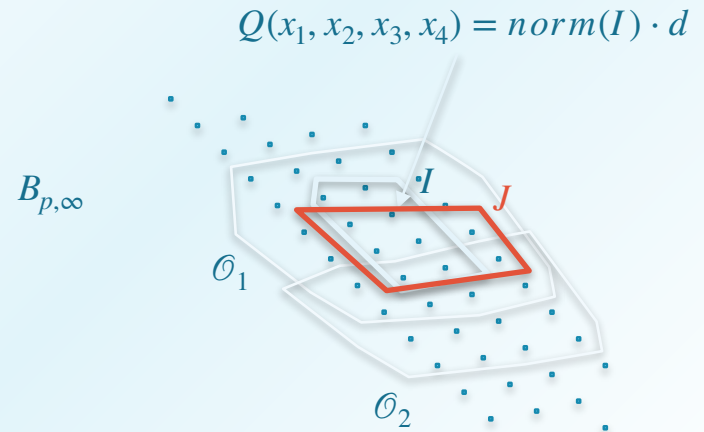

# Solving quadratic form: Cornacchia and Coppersmith

- Cornacchia algorithm is an algorithm for solving the Diophantine equation  $x_1^2 + \Delta x_2^2 = m$  where  $1 \leq \Delta < m$  and  $\Delta$  and  $m$  are coprime.
- Coppersmith algorithm is a method to find small integer zeroes of polynomials modulo a given integer.

$$\text{End}(E_1) = \mathcal{O}_1$$

$$\text{End}(E_2) = \mathcal{O}_2$$

# Cornacchia algorithm

- We guess  $x_3$  and  $x_4$ .
- Change of variables to get the form  $x_1^2 + \Delta x_2^2 = m$ .
- If  $m$  does not have too many prime factors, we get the solution. Otherwise, we make a new guess for  $x_3$  and  $x_4$ .

$$\text{End}(E_1) = \mathcal{O}_1$$

$$\text{End}(E_2) = \mathcal{O}_2$$

$$Q(x_1, x_2, x_3, x_4) = \text{norm}(I) \cdot d$$

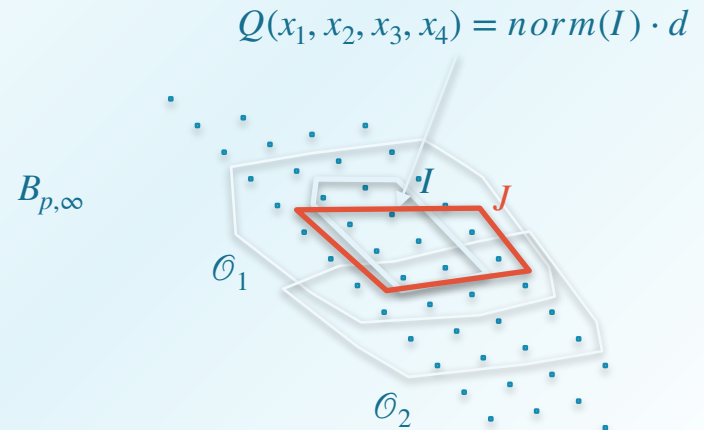

# Coppersmith algorithm

- Used in attacks on RSA when parts of the secret key are known.
- Multiple variants: Coppersmith, Coron, Bauer-Joux.
- We guess  $x_3$  and  $x_4$  (or only  $x_4$ ).

$$\text{End}(E_1) = \mathcal{O}_1$$

$$\text{End}(E_2) = \mathcal{O}_2$$

# Bivariate Coron

- Guess  $x_3$  and  $x_4$ .
- Get two algebraically independent polynomials.
- Obtain the root by computing resultants.

$$q(x, y) = 1 + a_{10}x + a_{01}y + a_{11}xy$$

$$W = \|q(xX, yY)\|_\infty$$

$$W \leq n < 2W$$

$$q_{ij}(x, y) = x^i y^j X^{k-1} Y^{k-j} q(x, y)$$

1	$x$	$y$	$xy$	$x^2$	$x^2y$	$y^2$	$xy^2$	$x^2y^2$
$XY$	$a_{10}X^2Y$ $XY$	$a_{01}XY^2$ $XY$	$a_{11}X^2Y^2$ $a_{01}XY^2$ $a_{10}X^2Y$ $XY$	$a_{10}X^2Y$  $X^2n$	$a_{11}X^2Y^2$  $a_{10}X^2Y$  $X^2Yn$	$a_{01}XY^2$    $Y^2n$	$a_{11}X^2Y^2$ $a_{01}XY^2$   $XY^2n$	$a_{11}X^2Y^2$      $X^2Y^2n$

# Bauer-Joux

- Guess  $x_4$ .
- Get three algebraically independent polynomials.
- Obtain the root by computing resultants.

$$p(x, y, z) = 1 + axy + byz$$

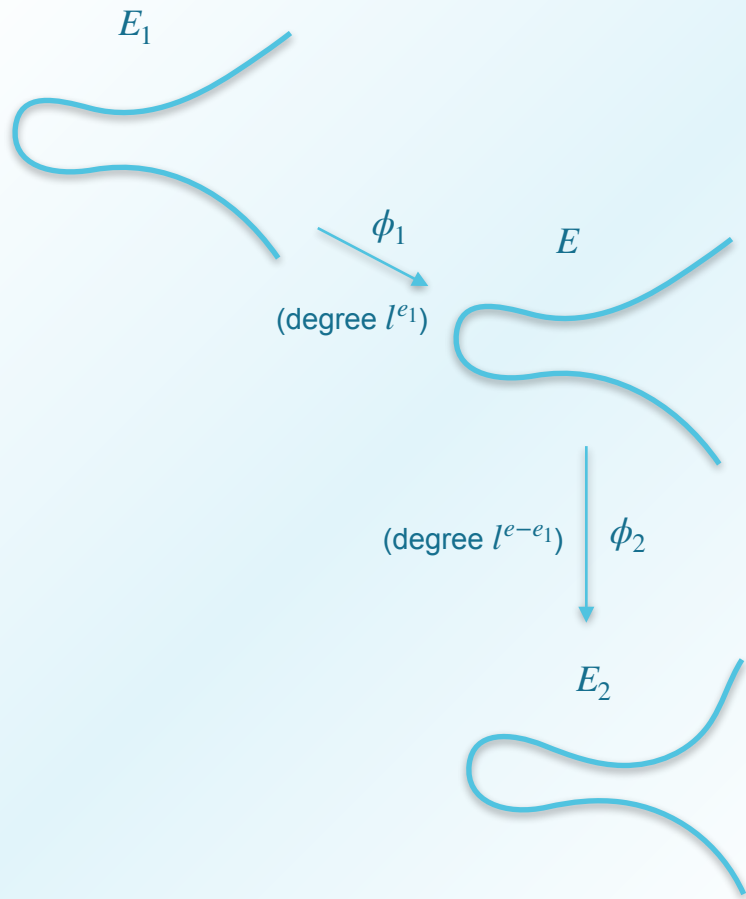

$$\begin{pmatrix} 1 & & & & & & & & & 1 & 0 \\ & X^{-1}Y^{-1} & & & & & & & & a & 0 \\ & & Y^{-1}Z^{-1} & & & & & & & b & 0 \\ & & & X^{-1} & & & & & & 0 & 1 \\ & & & & X^{-2}Y^{-1} & & & & & 0 & a \\ & & & & & X^{-1}Y^{-1}Z^{-1} & & & & 0 & b \end{pmatrix}$$

$$\begin{pmatrix} & & & & & & & & & 1 & 0 \\ & & & & & & & & & 0 & 1 \\ & & & & & & & & & 0 & 0 \\ & & & & & & & & & 0 & 0 \\ & & & & & & & & & 0 & 0 \\ & & & & & & & & & 0 & 0 \\ & & & & & & & & & 0 & 0 \end{pmatrix}$$

$$\begin{pmatrix} & & & & & & & & & 1 & 0 \\ & & & & & & & & & 0 & 1 \\ & & & & & & & & & b_1 & 0 \\ & & & & & & & & & b_2 & 0 \\ & & & & & & & & & b_3 & 0 \\ & & & & & & & & & b_4 & 0 \end{pmatrix}$$

# Hybrid approach

- $d = l^e \approx p^{\frac{1}{2}+e}$
- Guess  $l^{e_1}$ -isogeny  $\phi_1 : E_1 \rightarrow E$ .
- Use  $\phi_1$  to compute  $\text{End}(E)$  from  $\text{End}(E_1)$ .
- Solve the fixed-degree isogeny problem with  $E$  and  $E_2$  for degree  $l^{e-e_1}$  to obtain  $\phi_2$ , or guess again.
- Compose  $\phi_2$  with  $\phi_1$ .

# Results

- The best approach turned out to be the hybrid approach, it has a better time complexity than meet-in-the-middle algorithms in the range  $\frac{1}{2} \leq \epsilon \leq \frac{3}{4}$  on a classical computer.
- For quantum computers, Cornacchia provides the fastest quantum algorithm, with that we improve the time complexity in the range  $0 < \epsilon < \frac{5}{2}$ .
- Our strategy is essentially memory-free while meet-in-the-middle algorithms require exponential memory storage.

Method	Cost (classical)	Cost (quantum)	Condition on size
State-of-the-art (general d)	$\frac{1}{2} + \epsilon$	$\frac{1}{4} + \frac{\epsilon}{2}$	
State-of-the-art (large d)	$\frac{1}{2}$	$\frac{1}{4}$	$\epsilon > \frac{5}{2}$
State-of-the-art (smooth d)	$\frac{1}{4} + \frac{\epsilon}{2}$	$\frac{1}{4} + \frac{\epsilon}{2}$	
Cornacchia	$\max\{\frac{1}{2}, \epsilon\} + \log_p L[\frac{1}{3}]$	$\max\{\frac{1}{4}, \frac{\epsilon}{2}\}$	
Coppersmith (bivariate)	$\frac{1}{2}$	$\frac{1}{4}$	$\epsilon < \frac{1}{2}$
Coppersmith (trivariate)	$\frac{1}{2}$	$\frac{1}{4}$	$\epsilon < \frac{1}{4}$
Hybrid approach (smooth d)	$\max\{\frac{1}{2}, \epsilon - \frac{1}{8}\}$	$\frac{1}{4} + \frac{\epsilon}{2}$	$\frac{1}{4} < \epsilon < \frac{3}{4}$

# Open problem: no guessing

- Coron / Bauer-Joux on four variables.
- The problem of algebraic dependency of the polynomials.

Thank you!
