AI Research

Prove(x, w)
 $\rightarrow \pi$

zkSNARKs

Verify(x, π) $\rightarrow b$

Zero-Knowledge

π does not reveal
any information about w .

Proof of knowledge

In order to compute valid
 π , prover must know w .

Efficient Simulator
 $\mathcal{S}(x) \rightarrow \pi$

Malicious prover
 can run \mathcal{S}
 to compute π
 without knowing w

Efficient Extractor
 $\mathcal{E}(x, \pi) \rightarrow w$

Malicious verifier
 can run \mathcal{E}
 to learn
 full information on w

Simulator and extractor need a
superpower
 that malicious provers/verifiers don't have.

Prove(x, w)
 $\rightarrow \pi$

zkSNARKs

Verify(x, π) $\rightarrow b$

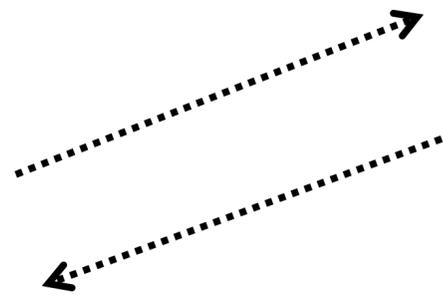

Simulation Extractability

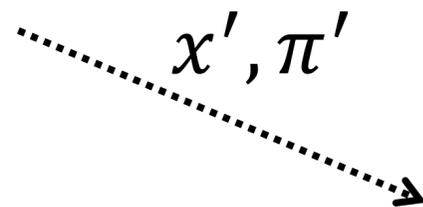

In order to compute valid π ,
 prover must *know* w , even after
 observing simulated proofs

\mathcal{A}^S

Efficient Simulator
 $\mathcal{S}(x) \rightarrow \pi$

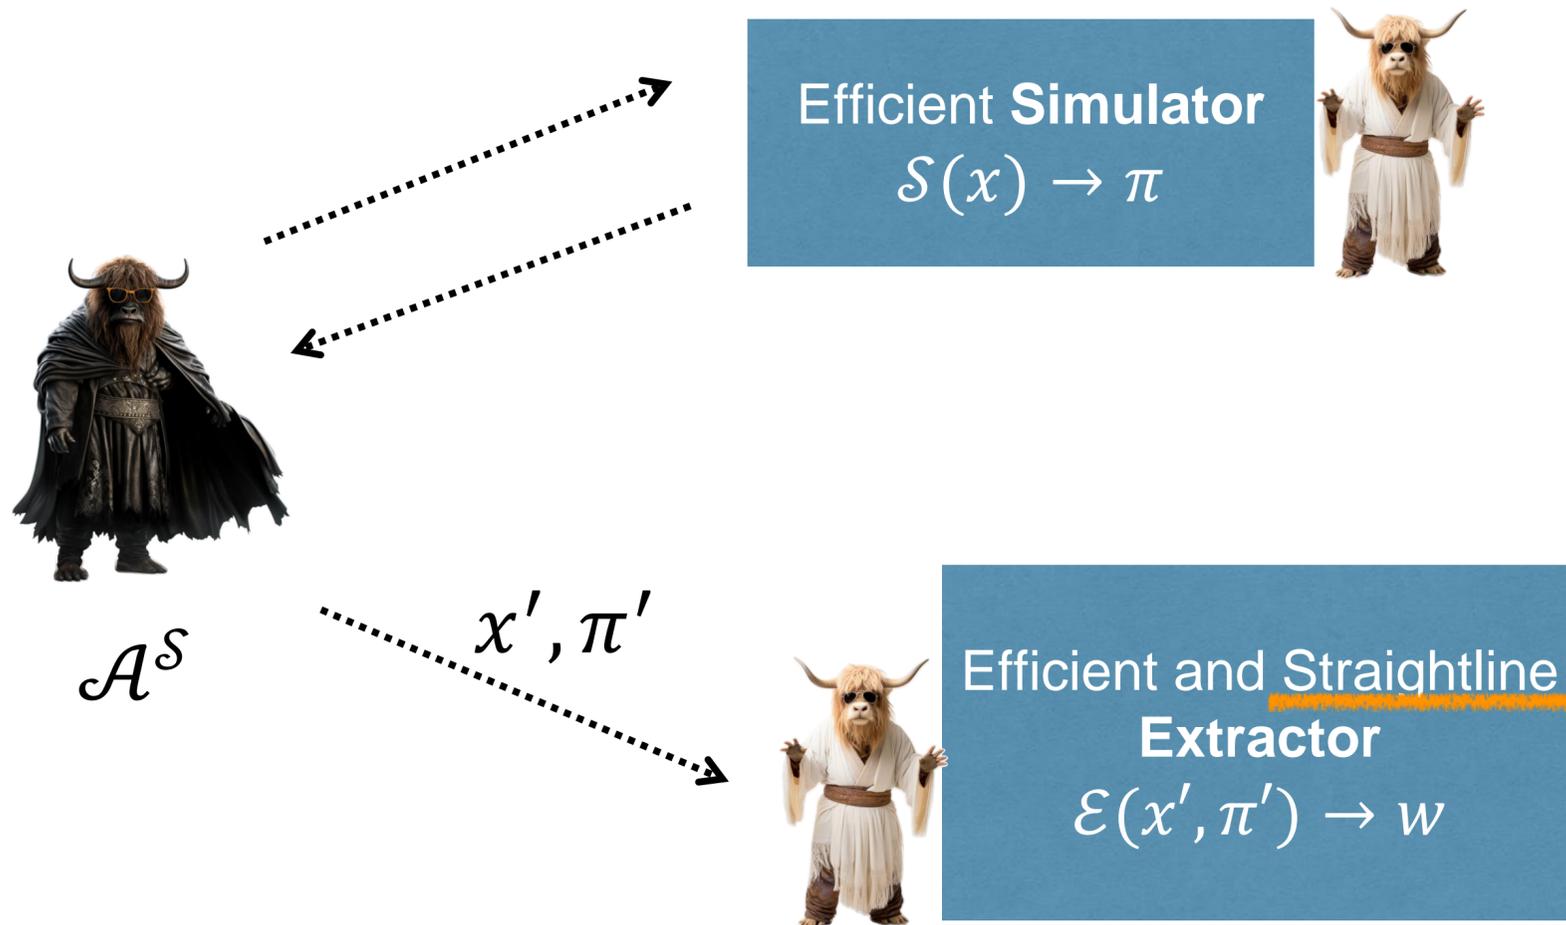

x', π'

Efficient Extractor
 $\mathcal{E}(x', \pi') \rightarrow w$

Sim-Ext is often a precondition of
UC-secure NIZK

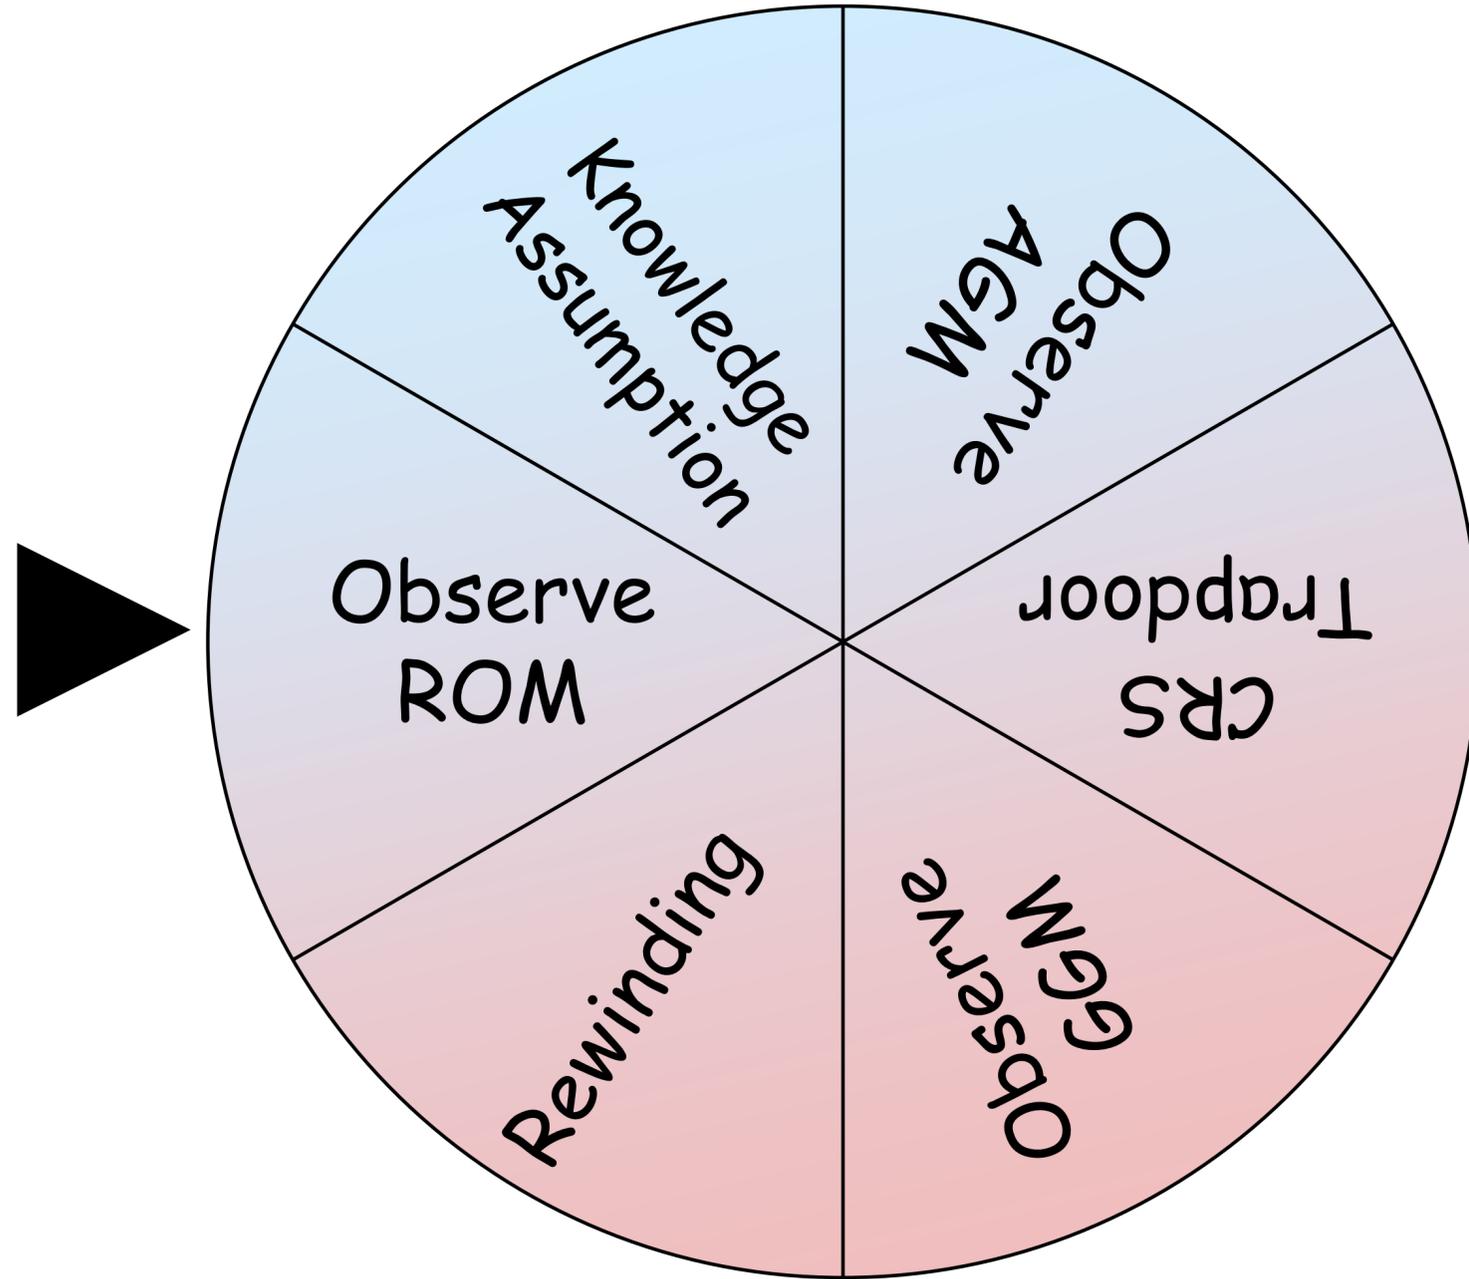

UC-Secure zkSNARKs

- Generic compilers turning NIZK with standalone proofs of security into UC-secure ones: [KZM+15] [ARS20] [BS21] [LR22] [CSW22] [AGRS23] [GKO+23]
- Incur overhead in proof sizes and/or prover time!
- Exception: [CF24] for hash-based, already-straightline-extractable SNARKs (previous talk)

Can we design a group-based idealized model allowing for **UC-secure SNARKs without overhead?**

Let's spin the PoK wheel

The UC RO hybrid model

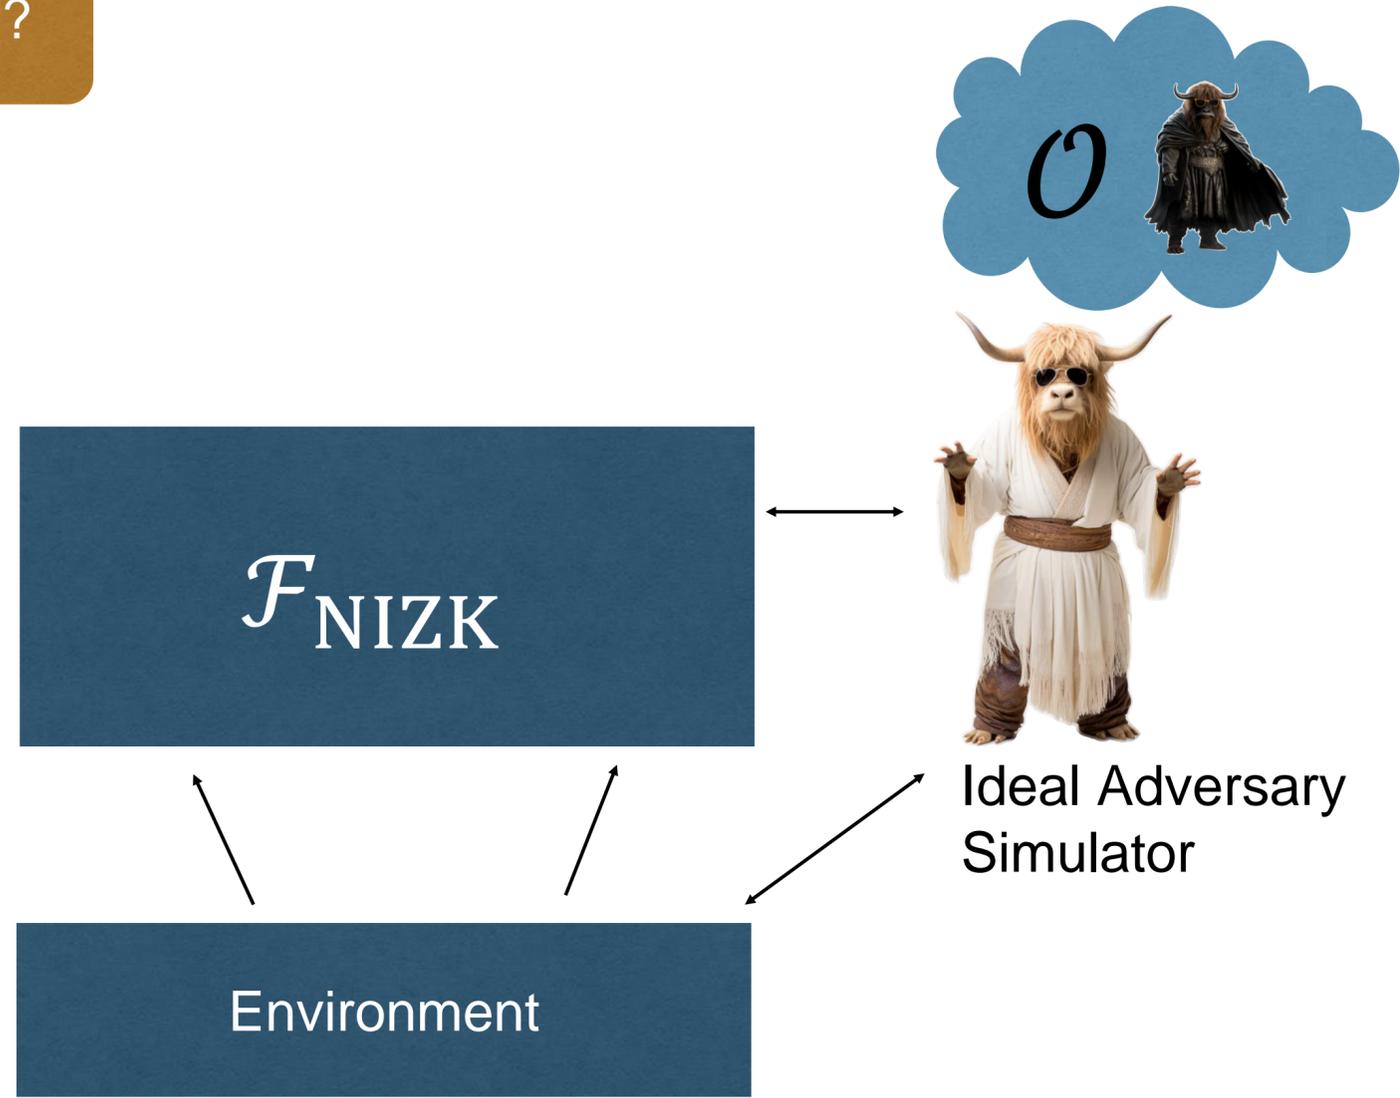

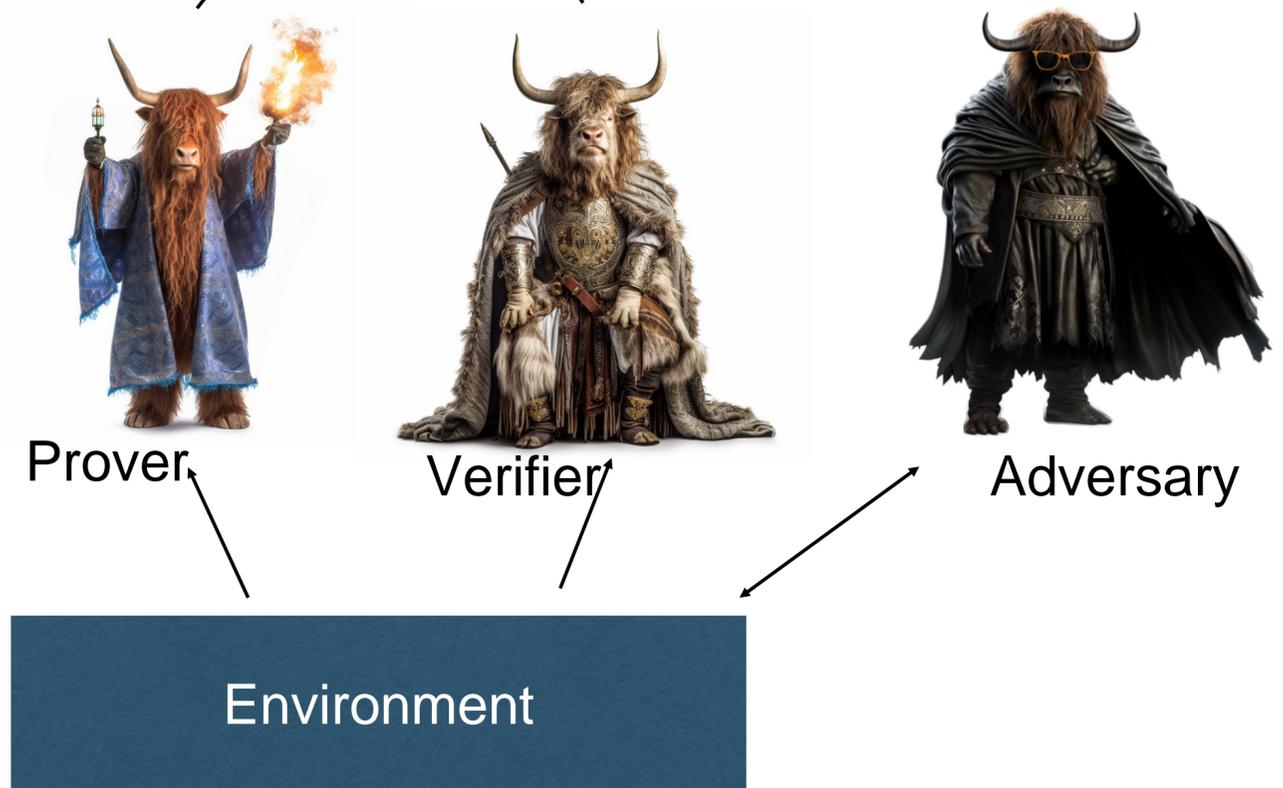

Real world

Ideal world

```
eval(x):  
if Q(x) = ⊥:  
  Q(x) ← {0,1}^n  
return Q(x)
```

\mathcal{O} Random oracle

Is this a good model?

Is this a good model?

Let's have two sessions of the protocol

Random Oracle

Random Oracle

\mathcal{O}

RO(123) = a03ab19b866fc

\mathcal{O}

RO(123) = 7106b623725f

Does *not* model sharing of \mathcal{O} with other protocols.

Adversary

What's RO(123) ?

Adversary

What's RO(123) ?

Environment

Superpower 1: Global Random Oracles

From
*Practical UC security
with a global random oracle*

Ran Canetti, Abhishek Jain, Alessandra Scafuro
CCS 2014

*The Wonderful World
of Global Random Oracles*

Jan Camenisch, Manu Drijvers, Tommaso Gagliardoni, Anja Lehmann, and Gregory Neven
Eurocrypt 2018

The better model: Global ROM

Global Random Oracle

$RO(123) = a03ab19b866fc$

All protocols share the same idealized resource!

Observability via domain separation:
Party in session s' queries $RO(s, 123)$
→ observable to everyone

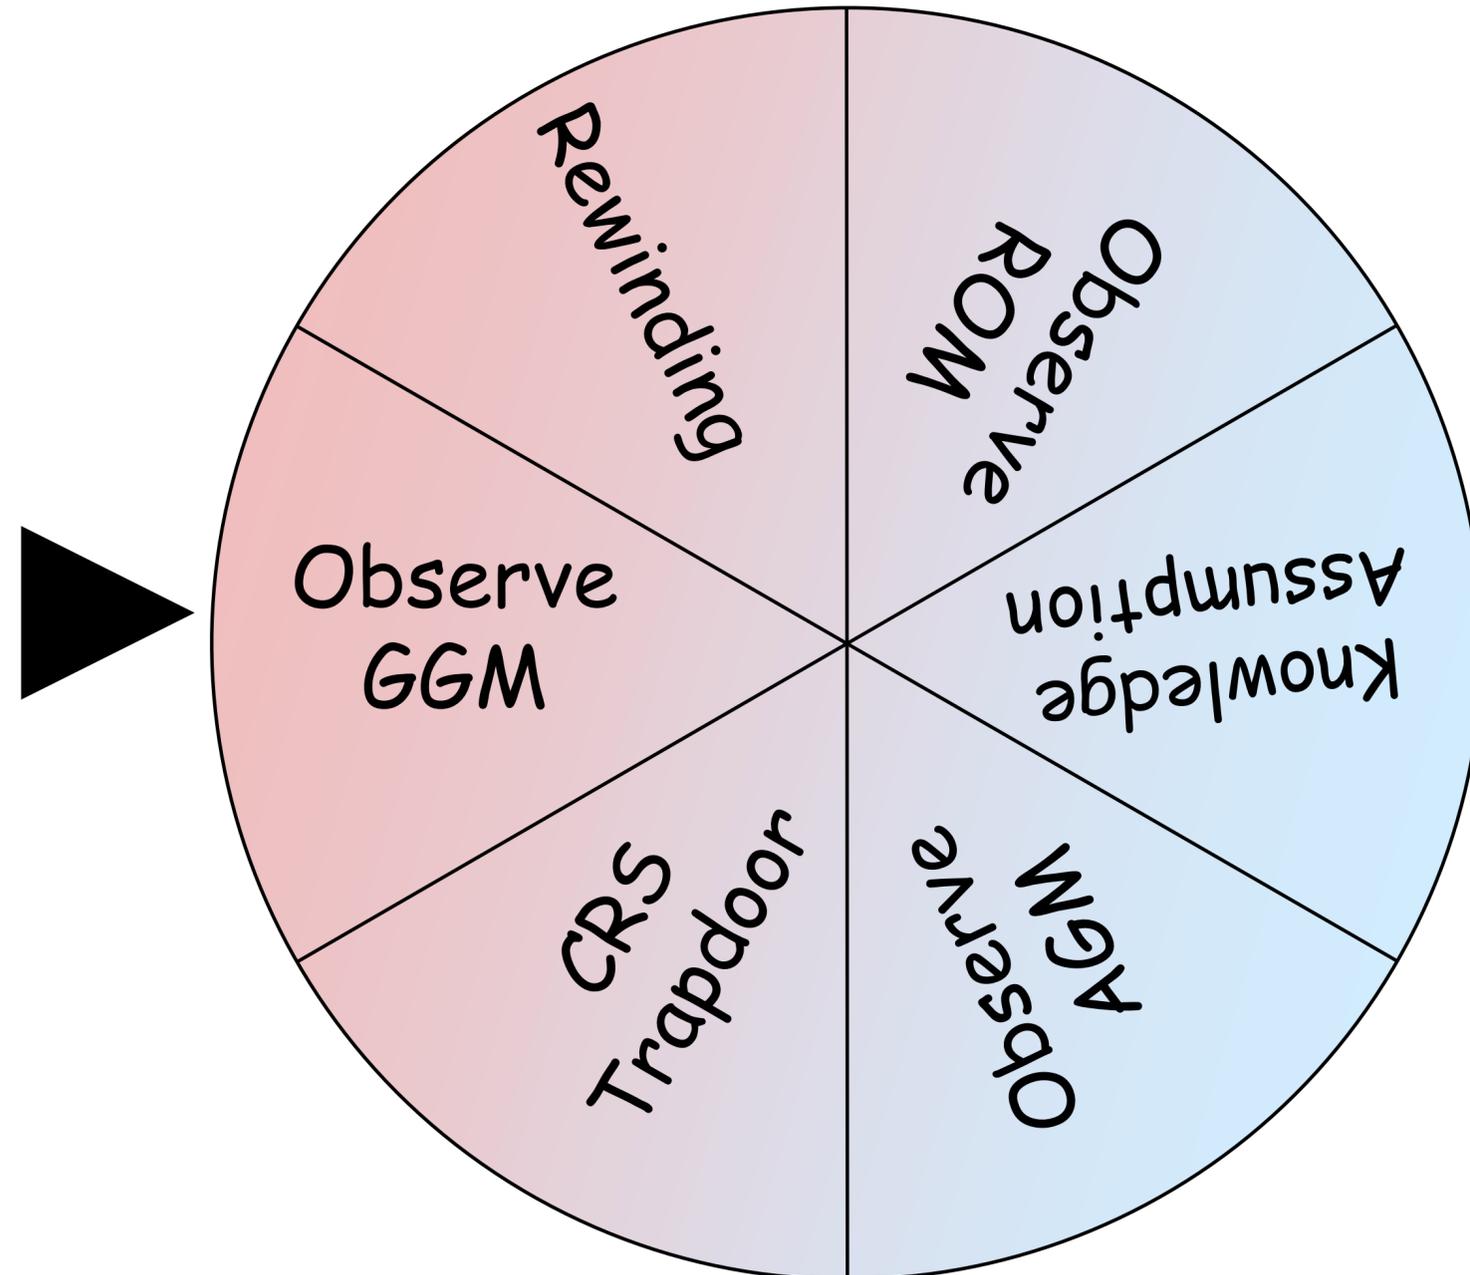

Adversary
What's $RO(123)$?

Adversary
What's $RO(123)$?

Environment

Let's spin the PoK wheel

The generic group model

- 🎯 Goal: model “**idealized**” group with no “extra” structure (just group operations[, pairing]).
- Similar to random oracles, which model “idealized” hash function with no structure.
- 💡 Idea: group elements get *random encoding* (= no structure), but **oracle enables group ops**.
- 👁️ Corollary: oracle sees all group ops.
- 🙈 PoK Extractor recovers witness from observed group ops

The generic group model

\mathcal{O} =

```
private random injective  $\tau: \mathbb{G} \rightarrow S$   
public generator  $g$   
  
 $op(g_1, g_2)$ :  
return  $\tau(\tau^{-1}(g_1) + \tau^{-1}(g_2))$ 
```

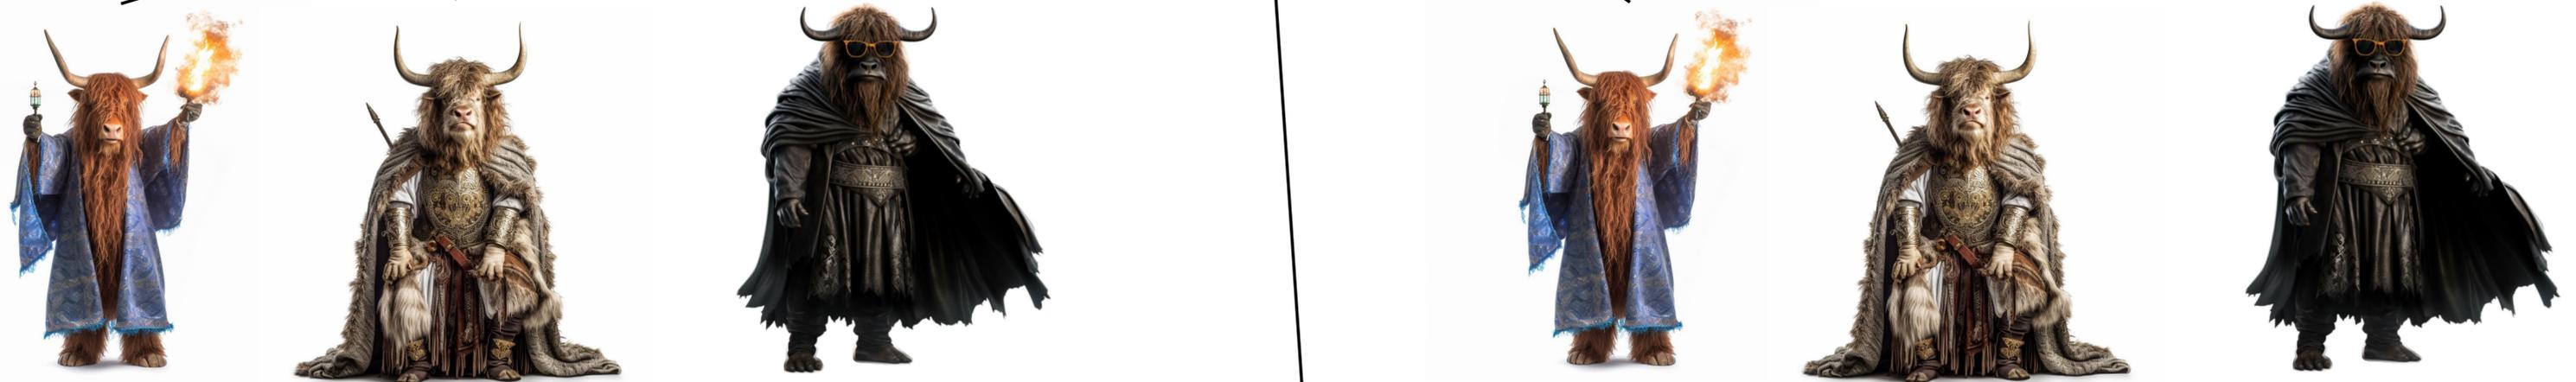

First Step: "Strict" Global GGM in UC

Global Generic Group Oracle

All protocols share the same idealized group!

$$g_3 \leftarrow \text{op}(g_1, g_2)$$

But PoK extractor can't observe ops!
Can we design observable GGG?

Adversary

What's $\text{op}(g_1, g_2)$?

Adversary

What's $\text{op}(g_1, g_2)$?

Environment

Example: Groth16 PoK in GGM

Extractor

observe()

$$A = \sum_{i=0}^m a_i [u_i] + [\alpha] + r[\delta]$$
$$B = \sum_{i=0}^m a_i [v_i] + [\beta] + r'[\delta]$$
$$C = \dots$$

Prover

Verifier

CRS: group elements $[u_i], [\alpha], [\beta], [\delta]$

Witness: wire values $a_i \in \mathbb{Z}_p$

[Check some pairing equations on A,B,C]

Design challenges

- 🧑‍🔧 Requirements:
 - 👁️ Simulator/Extractor **must see** group operations made by environment
 - Required to extract
 - 🚫 Environment **must not see** what group operations simulator makes
 - Would immediately reveal that we simulate
- ⚠️ First glance: **Impossible**
- 💡 Do **partial observability** via **domain separation**

Design challenges

- 🧑‍🔧 Requirements:
 - 👁️ Simulator/Extractor **must see** ^{relevant} group operations made by environment
 - Required to extract
 - 🚫 Environment **must not see** what group operations simulator makes
 - Would immediately reveal that we simulate
- ⚠️ First glance: **Impossible**
- 💡 Do **partial observability** via **domain separation**

Observation rules (intuition)

- 📄 Every session s gets its own group generator h_s
- 👍 Legal/unobservable: Session s operates on h_s
- 👎 Illegal/observable: Session s' operates on h_s

G-oGG: Observable Global Generic Group (Simplified)

private random inj. $\tau: \mathbb{G} \rightarrow S$
public rnd generator h_s for each session s
public poly variable X_s for gen of each session s
private representation $R[e]$ for each $e \in S$, initially $R[h_s] = X_s$

$op(g_1, g_2)$:

$s = \text{caller session}$

$result = \tau(\tau^{-1}(g_1) + \tau^{-1}(g_2))$

$R[result] = R[g_1] + R[g_2]$ //bookkeep sum of polynomials

if $R[result] \notin \mathbb{Z}_p[X_s]$: //invalid in caller session

 Add $(g_1, g_2, result)$ to public observation list

return $result$

Intuition

Cross-session operations
are observable

Example ops with caller session s

- $17X_s op X_{s'}$ observable
- $(17X_s + 3X_{s'}) op X_s$ observable
- $17X_s op 4X_s$ unobservable
- $(17X_s + 0X_{s'}) op X_s$
unobservable

Actual G-oGG

- Multiple generators per session
- Oblivious Sampling
-  Pairing operations

Summary: ROM vs GGM in UC

Local ROM: bad model 😞

Both sessions use SHA-3, why am I getting different hashes?

Local GGM: bad model 😞

Both sessions use BLS12-381, why are elements incompatible?

Global ROM: **lose observability.** Remodel.

Environment/other protocols can access global ROM without going through the simulator.

Global GGM: **lose observability.** Remodel.

Environment/other protocols can access global GGM without going through the simulator.

Domain separation:

$RO(s, x)$ is “valid/in-session”

iff caller is in session s .

Invalid queries are observable.

Domain separation:

$op(g_1, g_2)$ is “valid/in-session” iff g_1, g_2 are based on caller session’s generator h_s

ZK: honest parties only make “valid” unobservable queries within their domain.

PoK: when environment / protocol in session $s' \neq s$ queries related to domain s , it’s observable.

Groth16 proof challenges

Idea

Extract dlog representation of proof elements

Challenge

Cannot observe *everything* (only *my* session's generator(s))

💡 Solution

Argue that valid proofs cannot contain foreign generators

Extraction

Simulation

Idea

Use CRS trapdoor to generate proofs without witness

Challenge

Prover/Simulator GGM ops must not be observable

💡 Solution

Prover/simulator only operates on CRS elements

Takeaways

- New design of global generic groups in UC
- 👁️ To prove SNARKs UC-secure in GGGM, we need to explicitly **model observability**
 - **Not trivial!**
- Unlike UC-AGM [ABK+21], we introduce a **global GG** functionality while the original UC(GS) framework remains unchanged
- Case study: Get Groth16 SNARK in UC (against static corruptions) without modifications
