# Motivations

## Why HMAC ?

- Standardized and deployed in a lot of Internet protocols.
- Security proofs.

## SCA Attacks on HMAC

- DPA attacks on the hash function :
  - on MD4 and MD5 family, SHA family.
  - The internal states are figured out but isn't the value of  $k$ .

## Classical Countermeasures

- Randomization of the execution of the implementation.
- A new key for each new computation.

# Problematics

Can Side Channel Analysis be used in order to recover the whole HMAC secret key  $k$  with only 1 measure?

# Problematics

Can Side Channel Analysis be used in order to recover the whole HMAC secret key  $k$  with only 1 measure?

# Outline

- 1 Introduction
  - The Side Channel Leakage
  - The cryptographic target : HMAC
  - Our attack features
- 2 The Cryptanalysis
  - The leakage on SHA-1
  - The leakage on HMAC
  - The sketch of the attack
- 3 Practical experiments
  - The whole leakage
  - The hamming distances involved
- 4 Conclusion

# Prints of the internal cryptographic activity filter through

## Cryptographic Devices

- microprocessor,
- FPGA,
- smart card ...

## Side Channel

- 1 computational time,
- 2 power consumption,
- 3 electromagnetic radiations.

# The side channel leakage can be used to mount attack

## SCA Attacks

- Simple Power Analysis Attack (SPA),
- Template Analysis (TA),
- Differential Power Analysis Attack (DPA).

## SCA Software Countermeasures

- 1 SPA : power balanced implementation such as Montgomery Ladder,
- 2 DPA-TA : secret randomization and masking.

# HMAC features

The authentication code  $\text{HMAC}_k(M)$  is defined as:

$$\text{HMAC}_k(M) = H(\bar{k} \oplus \text{opad} || H(\bar{k} \oplus \text{ipad} || M)),$$

- opad and ipad are constant paddings.
- The secret key is manipulated twice:
  - $\bar{k} \oplus \text{opad}$ ,
  - $\bar{k} \oplus \text{ipad}$ .

# The Template Strategy

## Loading a value in a register

- The hamming distance leaks.

## Template-like Attack

- Software implementation with known assembly code.
  - The secret key  $k$  is split in  $l$  words of 32 bits each.
  - Each word is treated one after each other.
- EM near field techniques : template on hamming distance
  - 33 template traces for 33 possible hamming distances.
  - 1 operational EM trace to figure the hamming distance out.

## Secret recovery

- Load operations  $\Rightarrow$  constraints on secret words.
- The whole secret  $k$  is recovered with  $l \times 2^{32}$  computations.

## Attack validation

HMAC SHA-1 on a STRATIX FPGA (ALTERA) with a software implementation on a NIOS II.

## Goal of this section

### Assumption

The attacker is able to figure out the hamming distance during a load operation.

### Problematics

Is there enough loads in HMAC ?

## Detailed implementation

The message  $m$  is expanded in 80 words  $W_i$  with  $0 < i \leq 80$

- $W_i$  is a 32-bit word.
- $W_i = m_i$  for  $0 < i \leq l$

the compression function : repeat 80 times

- $P(A, B, C, D, E, W[i])$
- switch (A,B,C,D,E)

Values manipulated during the first rounds of SHA-1 only on the first message words

- the internal value  $A_1$  depend on  $m_0$ :
- $A_1$  leaks each time it is manipulated :
  - $B_2$  (copy),  $C_3$ ,  $D_4$  and  $E_5$  (after a rotation)

## 2 Conclusions about SHA-1

### 1<sup>st</sup> conclusion : recovering $k$ is a recurrence problem

- The internal values for the 1<sup>st</sup> call of  $P$  only depend on  $m_0$ .
- The internal values for the 2<sup>nd</sup> call of  $P$  only depend on  $m_1$  and  $m_0$ .
- The internal values for the  $i^{\text{th}}$  call of  $P$  only depend on  $m_j$  with  $j < i$ .

From now, we just focus on  $m_0$ .

### Function $P$ causes 8 load operations with $m_0$ -dependent values

- 3.5 bits of information for each load (hamming weight on 32 bits).
- $8 \times 3.5 = 28$  bits of constraint on  $W[0] = m_0$ .

## 2 Conclusions about SHA-1

### 1<sup>st</sup> conclusion : recovering $k$ is a recurrence problem

- The internal values for the 1<sup>st</sup> call of  $P$  only depend on  $m_0$ .
- The internal values for the 2<sup>nd</sup> call of  $P$  only depend on  $m_1$  and  $m_0$ .
- The internal values for the  $i^{\text{th}}$  call of  $P$  only depend on  $m_j$  with  $j < i$ .

From now, we just focus on  $m_0$ .

Function  $P$  causes 8 load operations with  $m_0$ -dependent values

- 3.5 bits of information for each load (hamming weight on 32 bits).
- $8 \times 3.5 = 28$  bits of constraint on  $W[0] = m_0$ .

## 2 Conclusions about SHA-1

### 1<sup>st</sup> conclusion : recovering $k$ is a recurrence problem

- The internal values for the 1<sup>st</sup> call of  $P$  only depend on  $m_0$ .
- The internal values for the 2<sup>nd</sup> call of  $P$  only depend on  $m_1$  and  $m_0$ .
- The internal values for the  $i^{\text{th}}$  call of  $P$  only depend on  $m_j$  with  $j < i$ .

From now, we just focus on  $m_0$ .

### Function $P$ causes 8 load operations with $m_0$ -dependent values

- 3.5 bits of information for each load (hamming weight on 32 bits).
- $8 \times 3.5 = 28$  bits of constraint on  $W[0] = m_0$ .

## But the key is manipulated twice in HMAC

- $m = \bar{k} \oplus \text{ipad}$  or  $m = \bar{k} \oplus \text{opad}$ .
- The secret key is used twice in the HMAC construction: it is used in the inner hash function as  $H(\bar{k} \oplus \text{ipad})$  and in the outer hash function as  $H(\bar{k} \oplus \text{opad})$ .
- $28 \times 2 > 32$  bits of constraints on  $k_0$ .

# SCA and the resulting Cryptanalysis

## The Side Channel Analysis

- Spy the register load operation with EM techniques.
- Find out the hamming distance between 2 consecutive register values.
- Deduce the hamming weight of internal values computed by the compression function.

## Cryptanalysis

- SCA gives constraints on hamming weights of words of  $\bar{k} \oplus \text{ipad}$  and  $\bar{k} \oplus \text{opad}$ .
- Constraints on  $(\bar{k} \oplus \text{ipad})_i$  and  $(\bar{k} \oplus \text{opad})_i$  with  $0 \leq i < l$  depend on  $k_j$  with  $0 \leq j < i$
- Find every  $k_i$ , one after each other.

# SCA and the resulting Cryptanalysis

## The Side Channel Analysis

- Spy the register load operation with EM techniques.
- Find out the hamming distance between 2 consecutive register values.
- Deduce the hamming weight of internal values computed by the compression function.

## Cryptanalysis

- SCA gives constraints on hamming weights of words of  $\bar{k} \oplus \text{ipad}$  and  $\bar{k} \oplus \text{opad}$ .
- Constraints on  $(\bar{k} \oplus \text{ipad})_i$  and  $(\bar{k} \oplus \text{opad})_i$  with  $0 \leq i < l$  depend on  $k_j$  with  $0 \leq j < i$
- Find every  $k_i$ , one after each other.

## Summary of the attack

- Each call to the function  $P$  induces 8 load operations of secret dependent values.
- Measuring the hamming distance gives 3.5 bits of information.
- If the values are sufficiently independent :  $8 \times 3.5 = 28$  bits of constraint on  $W[i]$ .
- Information on  $\bar{k} \oplus \text{ipad}$  and on  $\bar{k} \oplus \text{opad}$
- Enough information to guess  $k$  recursively by 32 bits and check if the guess is compliant with the hamming weight measured on each call of  $P$ .
- A key of size  $32 \times l$  bits will be figured out with  $l \times 2^{32}$  tries
- The algorithm still works if there is some errors in the measurement (less than 1.5 bits).

## Goal of this section

### Problematics

Is the attacker able to figure out the hamming distance during a load operation?

# HMAC implementation

Each call to the compression function is followed by a sleep of  $100\mu s$ .

## When one's should look at?

- The instruction

**ldw R2 (80) fp**

corresponds to the loading of  $W[0]$  in the register R2.

- CEMA on this instruction in order to localize the proper clock cycle.

# Extremal hamming distances

# Near hamming distances

# Cost of the attack

## Template profiling stage

- Around 20000 traces.
- A few CEMAs to time localize instructions.

## Template operational stage

- 1 trace.
- $4 \times 2^{32}$  on SHA-1 guesses to retrieve the whole 128-bit key .
- Tolerate an error of 1.5 bit.

# Conclusion

## Very efficient attack

- First attack which allow to retrieve the key on HMAC.
- Practical experiments have been done for validation.
- Only one curve is needed on a non-protected implementation.

## Logic countermeasure

- Precharging the target register with a random value.

# Thanks for your attention

# Do you have any questions ?
