Outline

- 1 The sponge construction
- 2 Sponge-based PRNG
- 3 Recent extensions and other applications
- 4 Building lightweight implementations
- 5 Improved security bounds
- 6 Building implementations that are even lighter
- 7 Conclusions

The sponge construction

- f : a b -bit permutation with $b = r + c$
- Operating mode:
 - **One** absorbing phase
 - **One** squeezing phase

The sponge construction: security

- Indifferentiability proof [Bertoni et al., Eurocrypt 2008]
 - Provably secure against attacks with $< 2^{c/2}$ calls to f
 - Proof assumes f is **random** permutation
- \Rightarrow Sponge secure if f has no exploitable properties

Sponge-based PRNG: the idea

- **Feed** seeding (and reseeding) material P_i
- **Fetch** pseudo-random strings z_i
- **Features:**
 - f invertible \Rightarrow no entropy loss
 - Forward secrecy: chop state by feeding back z_i

Sponge-based PRNG: the idea

- **Feed** seeding (and reseeding) material P_i
- **Fetch** pseudo-random strings z_i
- **Features:**
 - f invertible \Rightarrow no entropy loss
 - Forward secrecy: chop state by feeding back z_i

Sponge-based PRNG: the idea

- **Feed** seeding (and reseeding) material P_i
- **Fetch** pseudo-random strings z_i
- **Features:**
 - f invertible \Rightarrow no entropy loss
 - Forward secrecy: chop state by feeding back z_i

Sponge-based PRNG: security

- **Multiple** absorbing and squeezing phases...?!?
 - Is it secure?
 - What would be the model?

Our reference model for PRNG

- Using a public **random oracle**
- Input: sequence of *feed* and *fetch* requests
- Output of a *fetch* request
 - **must** depend on all seed material σ_i thus far
 - **may** depend on the *fetch* requests
 - $\mathcal{RO}(e(\text{history}))$, where e maps to \mathbb{Z}_2^*

Sponge-based PRNG revisited

- Can be modeled as multiple calls to a sponge function

Sponge-based PRNG: first call

- z_0 output of first call

Sponge-based PRNG: second call

- z_1z_2 output of second call

Sponge-based PRNG: third call

- z_3z_4 output of third call

Sponge-based PRNG: equivalent representation

- Sponge function takes the place of the random oracle
- Indifferentiability \rightarrow secure if f has no exploitable properties

Recent extension: the duplex mode

- **Duplex construction** [Bertoni et al., Duplexing the sponge, ..., SHA-3 workshop 2010]
 - Sibling to sponge construction, with equivalent security
 - **Object** with input and output in each call
- **Applications include**
 - Reseedable PRNG
 - Single-pass authenticated encryption
 - Overwrite mode

Building lightweight implementations

- Width of permutation f : $b = r + c$
- Trade-off between security and efficiency:
 - Security level: $c/2$ bits
 - Efficiency: r pseudorandom/seed bits per call to f
- Optimum trade-off depends on the usage scenarios
- Example 1: QUARK [Aumasson et al., QUARK, ..., CHES 2010]
- Example 2: KECCAK supports : $b \in \{25, 50, 100 \dots 1600\}$
 - Security level 80 bits implies $c = 160$
 - $b = 200$ gives rate $r = 40$
 - Compact in hardware [Bertoni et al., KECCAK main doc. 2.1]

New security bounds for sponge functions

- Resistance against state recovery [This paper]
 - Expected workload against passive adversaries: 2^c
 - Expected workload against active adversaries: $2^c / \text{data}$
- [Bertoni et al., On the security of the keyed sponge construction, SHA-3 workshop 2010]
 - Generalization of results of this paper
 - Indistinguishable from random oracle if $\text{data} \times \text{time} \leq 2^{c-1}$

Building implementations that are even lighter

- Sponge-based PRNG: passive adversary
 - Security level: c bits
 - Efficiency: r pseudorandom/seed bits per call to f
- Example with KECCAK
 - Security level 80 bits implies $c = 80$ rather than $c = 160$
 - $b = 200$ gives rate $r = 120$: speed $\times 3$
 - $b = 100$ gives rate $r = 20$: area divided by 2

...and secure against side channel attacks

[Bertoni et al., Building power analysis resistant implementations of KECCAK, SHA-3 workshop 2010]

- Secret sharing for robust protection against DPA
 - Suited for functions of low algebraic degree
 - KECCAK round function: degree 2 in GF(2)
- In software: two shares
 - Roughly doubles RAM usage and computation time
- In dedicated hardware: three shares
 - Trade-off between area and throughput
 - area $\times 4$: no loss of throughput
 - area $\times 2$: maximum throughput divided by 8

Conclusions

- Sponge functions are capable of all symmetric crypto operations:
 - Hashing, encryption, MAC, KDF, MGF (previously known)
 - Reseedable PRNG and authenticated encryption (new)
- Permutation can replace block cipher as crypto primitive!
- Sponge functions are suitable for embedded devices
 - Lightweight: QUARK and small- b KECCAK variants
 - Hardened: protection against DPA
